Executive summary

The HP Enterprise Virtual Array (EVA) storage¹ family has been designed for mid-range and enterprise customers with critical requirements to improve storage utilization and scalability. EVA arrays can fulfill application-specific demands for transactional I/O performance, while supporting easy capacity expansion, instantaneous replication, and simplified storage administration.

The combination of an EVA array, HP Command View EVA software and VMware vSphere 4 and 5 provides a comprehensive solution that can simplify management and maximize the performance of a vSphere infrastructure.

HP continues to develop and improve best practices for deploying HP EVA Storage arrays with vSphere 4 and 5. This white paper describes a broad range of best practices for a Fibre Channel (FC) implementation; iSCSI and Fibre Channel over Ethernet (FCoE) implementation are outside the scope of this paper.

Target audience: vSphere and SAN administrators that are familiar with the vSphere infrastructure and virtual storage features, the EVA array family, and Command View EVA.

DISCLAIMER OF WARRANTY

These are provided as a courtesy, free of charge, "AS-IS" by Hewlett-Packard Company ("HP"). HP shall have no obligation to maintain or support this software. HP MAKES NO EXPRESS OR IMPLIED WARRANTY OF ANY KIND REGARDING THIS SOFTWARE INCLUDING ANY WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, TITLE OR NON-INFRINGEMENT. HP SHALL NOT BE LIABLE FOR ANY DIRECT, INDIRECT, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES, WHETHER BASED ON CONTRACT, TORT OR ANY OTHER LEGAL THEORY, IN CONNECTION WITH OR ARISING OUT OF THE FURNISHING, PERFORMANCE OR USE OF THIS SOFTWARE.

The challenges

With vSphere 5, VMware continues to stretch the boundaries of scalability through features that include:

- Support for 1TB of RAM per virtual machine (VM)
- Support for 32 virtual CPUs per VM
- Support for 160 cores for host server
- High-performance SCSI virtual adapter
- Support for up to 512 VMs on a single ESX host²
- Modular storage stack that is closely integrated with the particular storage array

For administrators, this feature-packed hypervisor raises several questions about effectively configuring, tuning and deploying vSphere 4.x and 5.x in their respective SANs such as:

- What is the optimal storage configuration?
- Which I/O path policy is the most appropriate?
- How to simplify storage management, even in a complex environment with multiple storage systems?
- How to effectively monitor the SAN in order to quickly make adjustments when needed?

Successfully addressing these challenges is imperative if you wish to maximize the return on investment (ROI) for your SAN while continuing to meet the changing needs of the business. To help you achieve these goals, this paper presents best practices for configuring, tuning, and deploying a vSphere SAN environment.

² Depending on host server resources

Key concepts and features

This section introduces key concepts and features associated with the successful configuration, tuning, and deployment of a vSphere SAN environment. These include Asymmetric Logical Unit Access (ALUA) compliance, virtual disk (Vdisk) controller ownership and access, and Vdisk follow-over.

ALUA compliance

All EVA storage solutions – models P6x00, EVA8x00/6x00/4x00 – are dual-controller asymmetric active-active arrays that are compliant with the SCSI ALUA standard for Vdisk access/failover and I/O processing.

Note

ALUA is part of the SCSI Primary Commands – 3 (SPC-3) standard.

While the active-active nature of the array allows I/O requests to a Vdisk to be serviced by either controller, the array's asymmetry forces the optimal access path to the Vdisk to be used (that is, the I/O path to the controller that requires less processing overhead).

The controller with the optimal path to the Vdisk – managing controller – can issue I/Os directly to the Vdisk, whereas the non-managing controller – proxy controller – can receive I/O requests but must pass them to the managing controller to initiate fulfillment.

The following example shows how a read I/O request sent to the non-managing controller is processed:

- 1. The non-managing controller transfers the request (proxy) to the managing controller for the Vdisk.
- 2. The managing controller issues the I/O request to the Vdisk and caches the resulting data.
- The managing controller then transfers the data to the non-managing controller, allowing the request to be fulfilled via the controller/server ports through which the server initiated the request.

Thus, a proxy read – a read through the non-managing controller – generates processing overhead.

Note

Since write requests are automatically mirrored to both controllers' caches for enhanced fault tolerance, they are not affected by proxy processing overhead. Thus, the managing controller always has a copy of the write request in its local cache and can process the request without the need for a proxy from the nonmanaging controller.

Vdisk controller ownership and access

The ability to identify and alter Vdisk controller ownership is defined by the ALUA standard.

EVA arrays support the following ALUA modes:

- Implicit ALUA mode (implicit transition) The array can assign and change the managing controller for the Vdisk
- Explicit ALUA mode (explicit transition) A host driver can set or change the managing controller for the Vdisk

EVA arrays also support the following ALUA access types:

- Active-Optimized (AO) The path to the Vdisk is through the managing controller
- Active-Non-Optimized (ANO) The path to the Vdisk is through the non-managing controller

ALUA compliance in vSphere 4.x and 5.x

ALUA compliance was one of the major features added to the vSphere 4 SCSI architecture and remains standard in vSphere 4.1 and 5.x. The hypervisor can detect whether a storage system is ALUA-capable; if so, the hypervisor can optimize I/O processing and detect Vdisk failover between controllers.

vSphere 4.x and 5.x support all four ALUA modes:

- Not supported
- Implicit transitions
- Explicit transitions
- Both implicit and explicit transitions

In addition, vSphere 4.x supports all five ALUA access types:

- AO
- ANO
- Standby The path to the Vdisk is inactive and must be activated before I/Os can be issued
- Unavailable The path to the Vdisk is unavailable through this controller
- Transitioning The Vdisk is transitioning between any two of the access types defined above

The following load-balancing I/O path policies are supported by vSphere 4.x and 5.x:

- Round Robin ALUA-aware
- Most Recently Used (MRU) ALUA-aware
- Fixed I/O Not ALUA-aware

Because they are ALUA-aware, Round Robin and MRU I/O path policies first attempt to schedule I/O requests to a Vdisk through a path that includes the managing controller.

For more information, refer to Configuring multi-pathing.

Vdisk follow-over

Another important concept that must be understood is Vdisk follow-over, which is closely associated with ALUA.

As described above, ALUA defines which controller in an asymmetric active-active array is the managing controller for a Vdisk. In addition, follow-over ensures that, when the optimal path to the Vdisk changes, all hosts accessing the Vdisk change their access paths to the Vdisk accordingly.

Follow-over capability is critical in a vSphere 4.x and 5.x cluster, ensuring that Vdisk thrashing³ between controllers cannot occur. With follow-over, all vSphere servers⁴ accessing a particular Vdisk update their optimal Vdisk access paths accordingly when the Vdisk is implicitly moved from one controller to the other.

Configuring EVA arrays

HP provides tools to help you configure and maintain EVA arrays. For example, intuitive Command View EVA can be used to simplify day-to-day storage administration, allowing you to create or delete Vdisks, create data replication groups, monitor the health of system components, and much more. For batch operations, HP recommends using Storage System Scripting Utility (SSSU), a command-line tool that can help you quickly deploy large EVA configurations, back them up for future deployments, and perform advanced administrative tasks.

When configuring a large number of Vdisks for a vSphere 4.x and 5.x implementation, such as that described in this paper, you should configure the Vdisks to alternate between EVA controllers using either Path A-Failover/failback or Path B-Failover/failback (see <u>Vdisk provisioning</u>).

³ Backward and forward transitioning

⁴ Also known as ESX servers

<u>Appendix A – Using SSSU to configure the EVA</u> presents a sample script that creates multiple Vdisks, alternates path preferences between two controllers, and presents the Vdisks to vSphere servers.

This section outlines the following options for configuring an EVA array:

- Using Command View EVA
- Running Command View EVA within a VM
- Using the HP Insight Control Storage Module for vCenter

Using Command View EVA

Command View EVA can manage an array using one of the following methods:

 Server-based management (SBM) – Command View EVA is deployed on a standalone server that has access to the EVA storage being managed.

If desired, you can run Command View EVA within a VM, allowing you to clone this VM and use it as a template that can be quickly redeployed as needed, with minimal reconfiguration required.

When running Command View EVA in a VM, the following modes are supported:

- Virtualized SCSI mode The Command View EVA instance can only view the active path to LUN 0 on a single controller. This mode is enabled by default when you install Command View EVA 9.2 or later.
- VMDirectPath mode The Command View EVA instance bypasses the virtualization layer and can directly
 manage the EVA storage. This mode is supported on Command View EVA 9.3 or later.

For more information, refer to the VMware knowledge base article, "<u>Configuring VMDirectPath I/O for HP</u> <u>Command View EVA</u>."

Note

While this knowledge base article indicates that VMDirectPath mode is experimental, HP and VMware have agreed to support this feature.

 Array-based management (ABM) – For supported EVA models, Command View EVA can be deployed on the array's management module.

Running Command View EVA within a VM

Your ability to deploy Command View EVA within a VM may be impacted by the following:

- EVA model
- Command View EVA version being used
- Availability of a host bus adapter (HBA) that can be dedicated to the VM

Table 1 compares the options for deploying Command View EVA in a VM.

Requirement	Virtualized SCSI	VMDirectPath
Minimum EVA firmware	XCS 09534000 or later	All
Minimum Command View EVA software	9.2 or later	9.3 or later
Dedicated HBA required	No	Yes
Compatible EVA models	EVA8400 EVA6400 EVA4400 EVA4400-S P6300 P6500	EVA4100 EVA6100 EVA8100 EVA8400 EVA6400 EVA4400 EVA4400-S P6300 P6500
Command View EVAPerf support	No	Yes
SSSU support	Yes	Yes
VMware vMotion support	Yes	No

Table 1. Comparing requirements for Virtualized SCSI and VMDirectPath modes

Caveats for installing Command View EVA in a VM

If you are installing Command View EVA in a VM, take care where you deploy the VMware virtual disk hosting the operating system on which you plan to install Command View EVA. If you were to deploy this virtual disk on the same array that you intend to manage with the Command View EVA instance, any issue that causes the EVA array to be inaccessible would also impact your ability to identify this issue.

In general, when deploying Command View EVA in a VM, use a virtual disk on the vSphere host's local datastore, if available.

If you must deploy the Command View EVA VM on the SAN, then consider deploying two or more instances on two or more storage systems to increase availability in the event of an array failure.

Best practices for deploying Command View EVA in a VM with VMDirectPath I/O

- Deploy Command View EVA on the local datastore of the particular vSphere server.
- If a SAN-based Command View EVA deployment is required, then deploy instances on multiple arrays within the infrastructure to ensure the management interface remains available in the event the array hosting the VM for the primary Command View EVA instance becomes inaccessible.

For information on configuring VMDirectPath for use with Command View EVA, refer to <u>Appendix E – Configuring</u> <u>VMDirectPath I/O for Command View EVA in a VM</u>.

Using the Storage Module for vCenter

<u>HP Insight Control Storage Module for vCenter</u> is plug-in for vCenter Server that allows HP servers, storage, and networking to be managed from a single pane of glass that is integrated into the vSphere client.

Available at no cost from HP, the plug-in can be installed once for the entire vCenter environment using a single, allinclusive installer.

Key storage features of the plug-in include:

- Monitoring the status and health of HP storage arrays
- Providing detailed views of the relationships between the virtual and physical environment
- Automated provisioning of datastores and VMs
 - Adding, removing, and expanding datastores
 - Creating VMs from templates on new datastores
 - Using array-based snapshot and snap clone technologies to clone VMs

Figure 1 shows the overview screen for the HP Insight Control Storage Module for vCenter plug-in.

The Storage Module for vCenter can enhance VMware functionality by providing detailed views of the relationships between the virtual and physical environments. Understanding the physical infrastructure helps you make betterinformed decisions when you are designing, deploying, maintaining, and troubleshooting a virtual environment.

The plug-in can provide detailed information about the mapping between a VM and the disks on which its data resides. This information can be important – for example, to ensure that a production database application is located within a particular array on RAID 1 storage that is being replicated to a remote data center. This level of visibility previously required you to manually track mappings between storage and virtual objects using large spreadsheets.

Figure 2. Mapping from the virtual to physical environment with the Storage Module for vCenter

Storage Disks Virtual Disks Hosts Paths Replications

Storage Disks for Virtual Machine ESX_VM01

Add/Remove Columns...

Array Disk Name	Array Name	\$Array Ty	\$Datasto	Type
Virtual Disks\Viper\ESX-ABC\E1_D02_A	Calamity E	HP EVA	[DS 501] E	
Virtual Disks/Viper/ESX-ABC/E1_D02_A	Calamity_E	HP_EVA	[DS 501] E	
\Virtual Disks\Viper\ESX-ABC\E1_D04_A	Calamity_E	HP_EVA	DS 501	Datastore
\Virtual Disks\Viper\ESX-ABC\E1_D05_A	Calamity_E	HP_EVA	DS 501	Datastore

The Storage Module for vCenter also provides automated provisioning for datastores and VMs. After the storage administrator has configured the plug-in to support automated provisioning for specific EVA disk groups, the VMware administrator can then perform automated storage provisioning operations – quickly, without requiring the assistance of the storage administrator.

Best practice for mapping virtual objects to storage and for monitoring and provisioning storage

• Use the Storage Module for vCenter to save time and improve efficiency by mapping, monitoring, provisioning, and troubleshooting EVA storage directly from vCenter.

For more information on the Storage Module for vCenter, refer to the <u>HP Insight Control for VMware vCenter Server</u> <u>User Guide</u>.

Array hardware configuration and cabling

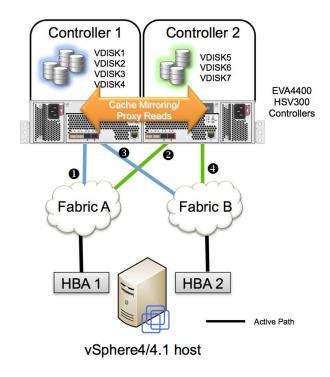

Best practices for EVA hardware configuration and cabling are well defined in the <u>HP 6400/8400 Enterprise Virtual</u> <u>Array user guide</u> and, thus, are not described in great detail in this paper.

However, it is important to note that when configuring vSphere to access an EVA array, HP highly recommends creating a redundant SAN environment by leveraging the following components:

- Redundant controllers on the EVA array
- Redundant Fibre Channel SANs
- At a minimum, dual HBAs in each ESX host

The resulting topology should be similar to that presented in Figure 3, which shows a vSphere 4.x server attached to an EVA4400 array through a redundant fabric.

Figure 3. Highly-available EVA/vSphere 4.x SAN topology

The benefits of this topology include the following:

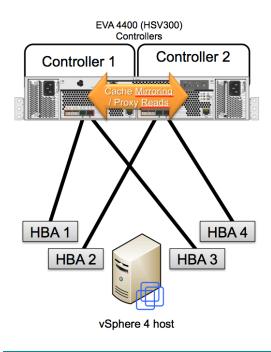

- The topology provides increased fault tolerance, with protection against the failure of an HBA, a single fabric, or a controller port or controller.
- As described earlier, it is a best practice to access the Vdisk through the managing (optimal) controller for read I/O. Thus, in the event of an HBA failure, failover occurs at the HBA-level, allowing the Vdisk to remain on the same controller.

For this reason, HP highly recommends configuring each HBA port in the ESX server to access one or more ports on each controller.

- Similarly, a controller failure only triggers a controller failover and does not cause an HBA failover, reducing system recovery time in the event of a failure.
- A fabric failure does not trigger a controller failover or force the use of the proxy path.

In a direct-connect environment, the same principles can be achieved with two more HBA or HBA ports; however, the configuration is slightly different, as shown in Figure 4.

Figure 4. EVA/vSphere 4.x and 5.x direct-connect topology

If the direct-connect configuration were to use two rather than four HBA ports, there would be a one-to-one relationship between every HBA and controller. Thus, a controller failover would result in an HBA failover and vice versa, creating a configuration that is not ideal.

In order to implement the recommended topology shown in Figure 3, all vSphere hosts must have their EVA host profiles set to **VMware** in Command View EVA, as shown in Figure 5.

Comments:							

Note

When configuring VMware Consolidated Backup (VCB) with an EVA array, all vSphere hosts must be set to **VMware**. However, the VCB proxy host, which is a Microsoft® Windows® server attached to the EVA, must be set to **Microsoft Windows** (Windows Server 2003) or **Microsoft Windows 2008** (Windows Server 2008).

Disk group provisioning

An EVA disk group is the largest storage object within the EVA storage virtualization scheme and is made up of a minimum of eight physical disks for FC, SAS or FATA drives and 6 for SSD drives. Within a disk group, you can create logical units of various sizes and RAID levels.

Note

An EVA RAID level is referred to as VraidX. The EVA array allows Vraid0, Vraid1, Vraid5, and Vraid6 logical units to coexist in the same disk group on the same physical spindles. Not all EVA models support all disk drive types mentioned above. SSD drives require their own disk group. FATA drives require their own disk group. FC drivers require their own disk group. SAS drives require their own disk group.

When configuring an EVA disk group for vSphere 4.x and 5.x, you should keep in mind the following important factors:

- Formatted capacity
- Sparing overhead and drive failure protection level
- Application being virtualized
- Storage optimization requirements

Formatted capacity

Although disk capacity is typically referred to in round, integer numbers, actual storage capacity in an EVA is tracked in binary form; thus, the formatted capacity of a drive may be slightly smaller than its nominal capacity. For example, a drive with a nominal capacity of 146 GB provides 136.73 GB of formatted capacity, approximately 6.5% less.

Sparing overhead and drive failure protection level

Sparing overhead in an EVA array is defined as the amount of space that must be reserved to be able to recover from physical disk failures within a disk group. Unlike other storage systems, which set aside specific disks as spare drives, the EVA spreads the spare space⁵ across all the disks within a group. The EVA sparing implementation eliminates the possibility of an assigned spare disk failing when it is needed for recovery.

The overhead created by sparing is calculated as follows:

Sparing capacity = (Size of largest disk in disk group * 2) * (Protection level)

In this formula, the value for disk drive failure protection level (Protection level) may be as follows:

- None
- Single The disk group survives the failure of a single disk
- Double The disk group survives the failure of two disks

⁵ Also known as reconstruction space

You can use Command View EVA to set a disk drive failure protection level in the properties for the particular disk group, as shown in Figure 6.

Figure 6. Disk protection level as seen in Command View EVA

Disk drive failure j	notection
Requested level:	Double -
Actual level:	None Single
Occupancy	Double
Total:	833 GB
Alarm level:	90 %

Note

Vraid0 Vdisks are not protected.

For a disk group where the largest disk drive capacity is 146 GB and double disk drive failure protection is required, sparing capacity can be calculated as follows:

Sparing capacity = (136.73 * 2) * 2 = 546.92 GB

Sparing does not span disk groups; each disk group must be allocated its own sparing space based on the above formula.

Application-specific considerations

One of the most common misconceptions about server virtualization is that when an application is virtualized, its storage requirement can be reduced or changed. In practice, due to the aggregation of resources, virtualization typically increases the storage requirement. Thus, when you virtualize an application, you should maintain the storage required by this application while also provisioning additional storage for the virtual infrastructure running the application.

Sizing storage for any application that is being virtualized begins with understanding the characteristics of the workload. In the white paper, "<u>HP P6000 EVA using VMware vCenter Site Recovery Manager</u>," HP describes how to determine the number of disks needed to support a particular application. The following formula is used to calculate the spindle count required for a random access workload:

 $Number of drives needed = \frac{(Total IOPS * RAID penalty * Write\%) + (Total IOPS * Read\%)}{Raw performance of the disk drive}$

In this formula, the Total IOPS value and read/write ratio are application-dependent.

The **RAID penalty** value is defined as the number of I/Os to disk that result from a guest I/O due to the particular Vraid level being used. For example, every I/O request to a Vraid1 Vdisk results in two I/Os being issued in the array in order to provide data protection.

Best practice for sizing an EVA disk group

• When sizing an EVA disk group, start by determining the characteristics of the application's workload, which will help you optimize array performance.

Storage optimization requirements

In addition to the number of disks required to handle the performance characteristics of the particular application, you must also account for the total storage capacity required by the applications and VMs being deployed.

This storage capacity can be determined by simple arithmetic by adding the storage requirements for each VM to the capacity required for the various applications. However, depending on your particular storage optimization objective, the actual formatted capacity yielded can be lower than the simple aggregation of the required number of EVA drives.

HP defines three storage optimization schemes, each of which is subject to specific storage overhead and deployment considerations:

- Cost
- Availability
- Performance

Optimizing for cost

When optimizing for cost, you goal is to minimize the cost per GB (or MB). Thus, it makes sense to minimize the number of disk groups; in addition, since the cost per GB is lower as drive capacity increases, it is best to use the largest disks of the same capacity within a particular disk group.

Even if you have disks with different capacities, it is better to use them in a single disk group rather than creating multiple disk groups.

Best practice for filling the EVA array

• To optimize performance, fill the EVA with as many disks as possible using the largest, equal-capacity disks. Note that the use a few larger drives with many small drives is inefficient due to sparing considerations.

Optimizing for availability

When optimizing for availability, your goal is to accommodate particular levels of failures in the array.

Availability within the array – and its usable capacity – can be impacted by a range of factors, including:

- Disk group type (enhanced or basic)
- Vdisk Vraid type
- Number and variety of disks in the disk group
- Protection levels
- Use of array-based copies

Typically, the additional protection provided by using double disk drive failure protection at the disk group-level cannot be justified given the capacity implications; indeed, single disk drive failure protection is generally adequate for most environments.

Enhanced disk groups offer features such as:

- Vraid6 protection, along with the traditional EVA Vraid0, 1, and 5
- Additional metadata protection, which is associated with a further storage capacity overhead

Many database applications use Vraid1 for database log files to guarantee performance and availability. However, while providing stronger data protection than Vraid5, Vraid1 has a much higher storage cost.

Best practice for protecting the disk group

• Single disk drive protection is sufficient for a disk group unless the mean time to repair (MTTR) is longer than seven days.

Best practices for using Vraid

- Only use Vraid6 when it is a requirement for your deployment.
- Vraid5 comes at a lower storage-capacity cost and provides adequate redundancy for most ESX 4.x deployments.

Optimizing for performance

When optimizing for performance, your goal is to drive as much performance as possible from the system.

However, configuring for optimal performance may have an impact on usable storage capacity. For example, it may be desirable to segregate small random workloads with short response time requirements from sequential workloads. In this use case, you should create two disk groups, even though this configuration would create additional sparing capacity utilization and reserved sparing capacity within each disk group.

Best practice for using disks of various performance characteristics

• When using disks of varying performance characteristics, use a single disk group rather than multiple disk groups.

Summary

• The use of a single EVA disk group is typically adequate for all storage optimization types (cost, performance, capacity).

Refer to the HP white paper, <u>HP 4400/6400/8400 Enterprise Virtual Array configuration</u> for additional information on storage optimization.

Vdisk provisioning

All EVA active-active arrays are asymmetrical and comply with the SCSI ALUA standard.

When creating a Vdisk on an EVA array, you have the following options for specifying the preference for the managing controller for that Vdisk:

• No Preference

- Controller ownership is non-deterministic; Vdisk ownership alternates between controllers during initial
 presentation or when controllers are restarted.
- On controller failover (owning controller fails), Vdisks are owned by the surviving controller.
- On controller failback (previous owning controller returns), Vdisks remain on the surviving controller; no failback occurs unless explicitly triggered.

Path A-Failover only

- At presentation, the Vdisk is owned by Controller A.
- On controller failover, the Vdisk is owned by Controller B.
- On controller failback, the Vdisk remains on Controller B; no failback occurs unless explicitly triggered.

Path A-Failover/failback

- At presentation, the Vdisk is owned by Controller A.
- On controller failover, the Vdisk is owned by Controller B.
- On controller failback, the Vdisk is owned by Controller A.

Path B-Failover only

- At presentation, the Vdisk is owned by Controller B.
- On controller failover, the Vdisk is owned by Controller A.
- On controller failback, the Vdisk is owned by Controller A; no failback occurs unless explicitly triggered.

• Path B-Failover/failback

- At presentation, the Vdisk is owned by Controller B.
- On controller failover, the Vdisk is owned by Controller A.
- On controller failback, the Vdisk is owned by Controller B.

In the event of a controller failure that triggers the failover of all owned Vdisks to the alternate controller, it is critical that, when the failed controller is restored, Vdisk ownerships that were failed over to the surviving controller are failed

back to the restored controller. This action ensures that, after a controller failover, the system can return to its default balanced/configured state and that all Vdisks do not end up on a single controller, degrading system performance.

With vSphere 4.x and 5.x and earlier versions of ESX, it is highly recommended to use one of the following preferences when configuring EVA Vdisks:

- Path A-Failover/failback
- Path B-Failover/failback

These preferences ensure that Vdisk ownership is restored to the appropriate controller when a failed controller is restored.

Vdisks should be created with their controller failover/failback preference alternating between Controller A and B.

The above recommendations provide additional benefits in a multi-pathing configuration, as described in <u>Configuring</u> <u>multi-pathing</u>.

Best practice controller ownership

• Controller ownership for EVA Vdisks should alternate between Controller A and Controller B, using the Path-A-Failover/Failback or Path-B-Failover/Failback setting.

Implementing multi-pathing in vSphere 4.x and 5.x

A key task when configuring vSphere 4.x and 5.x is to set up multi-pathing so as to optimize the connectivity and operation of the EVA array. In addition, advanced tuning of HBAs, virtual SCSI adapters and ESX advanced parameters can help you increase storage performance.

vSphere 4 introduced the concept of path selection plug-ins (PSPs), which are essentially I/O multi-pathing options. These plug-ins are described in more detail in <u>Configuring multi-pathing</u>.

Table 2 outlines multi-pathing options in vSphere 4.x and 5.

I/O path policy	PSP	vSphere 4	vSphere 4.1	vSphere 5
MRU	VMW_PSP_MRU	Yes	Yes	Yes
Round Robin	VMW_PSP_RR	Yes	Yes	Yes
Fixed	VMW_PSP_FIXED	Yes	Yes	Yes
Fixed_AP (Array Preference)	VMW_PSP_FIXED_AP	No	Yes	(Fixed = Fixed_AP) ⁶

 Table 2. Multi-pathing options

The I/O path policies supported since vSphere 4.x are as follows:

• MRU

- ALUA-aware
- Gives preference to the optimal path to the Vdisk
- If all optimal paths are unavailable, MRU uses a non-optimal path
- When an optimal path becomes available, MRU fails over to this path
- Although vSphere servers may use a different port through the optimal controller to access the Vdisk, only a single controller port is used for Vdisk access per vSphere server

⁶ On vSphere 5.x, the FIXED I/O path policy when attached to an ALUA capable array operates like the FIXED_AP policy in vSphere 4.1.

Round robin

- ALUA-aware
- Queues I/O to Vdisks on all ports of the owning controllers in a round robin fashion, providing instant bandwidth improvement over MRU
- Continues queuing I/O in a round robin fashion to optimal controller ports until none are available, at which time it fails over to non-optimal paths
- When an optimal path becomes available, round robin fails over to it
- Can be configured to round robin I/O for a Vdisk to all controller ports by ignoring the optimal path preference

Note

Using round robin policy and ignoring the optimal path preference may be beneficial when you need to increase controller port bandwidth to accommodate a write-intensive workload.

Fixed

- Not ALUA-aware
- Subject to the same intricate configuration considerations as ESX 3.5 or earlier
- May result in a configuration where the non-optimal I/O path to a logical unit is used for I/O
- Not recommended for use with vSphere 4.x and an EVA array

• Fixed_AP

Introduced in vSphere 4.1, Fixed_AP I/O path policy extends the functionality of Fixed I/O path policy to activepassive and ALUA-compliant arrays. Fixed_AP can also identify the preferred controller for a Vdisk.

Despite being ALUA-aware, the primary path selection attribute for Fixed_AP for ALUA capable arrays is the preferred controller for a Vdisk and not just its access state.

To summarize, the key capabilities of Fixed_AP include:

- ALUA aware
- Gives preference to the optimal path to a Vdisk
- Changes the access state of a Vdisk but not its PREF setting
- If all optimal paths are unavailable, Fixed_AP uses a non-optimal path and makes it optimal
- If all non-optimal paths are unavailable, Fixed_AP uses an optimal path
- If the path being used is non-optimal but preferred, Fixed_AP attempts to make this path optimal
- Although vSphere servers may use a different port through the optimal controller to the Vdisk, only a single controller port is used for Vdisk access per vSphere server
 - Starting with vSphere 5, the functionality of the FIXED_AP I/O path policy has been merged with the legacy Fixed I/O path policy. So when connected to an ALUA capable storage array, the Fixed I/O path policy in ESXi 5.x will behave like Fixed_AP did in ESX 4.1 and revert to legacy Fixed I/O path policy when connected to non-ALUA storage arrays.

Implementing multi-pathing

Since vSphere 4.x and 5.x are ALUA-compliant, their implementation of multi-pathing is less complex and delivers higher levels of reliability than ESX 3.5 or earlier.

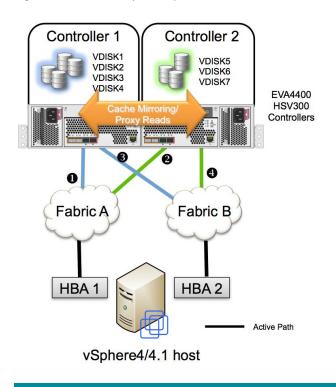

Setting up multi-pathing only requires the following steps:

- Configure the Vdisk
- Select the controller access policy at the EVA
- Power on/reboot all vSphere 4.x/5.x servers or perform a rescan

Following the boot or rescan, vSphere 4.x detects the optimal access paths and, if MRU, round robin I/O or Fixed_AP path policy has been selected, gives optimal paths the priority for issuing I/Os.

Figure 7 shows a typical multi-pathing implementation using vSphere 4.x/5.x.

Figure 7. EVA connectivity with vSphere 4.x/5.x

All I/Os to Vdisks 1 – 4 are routed through one or more ports on Controller 1 and through Paths ① and/or ②, regardless of the HBA that originates the I/O. Similarly, all I/Os to Vdisks 5 – 7 are routed to Controller 2 through Paths ② and/③, regardless of the originating HBA.

The vSphere 4.x/5.x implementation yields much higher system resource utilization and throughput and, most importantly, delivers a balanced system out of the box, with no intricate configuration required.

Note

From the perspective of Vdisk access, you can easily balance vSphere 4.x with an EVA array. However, it may be desirable to capture performance metrics at the EVA and assess data access to/from each controller to ensure that the workload is truly balanced between the two controllers.

Using Fixed_AP I/O path policy

Because it is ALUA-aware, Fixed_AP I/O path policy can extend the functionality of Fixed I/O path policy to activepassive and ALUA-aware arrays. In addition, Fixed_AP can identify the preferred controller for a Vdisk.

Despite being ALUA aware, Fixed_AP's primary path selection attribute is the preferred controller setting of a Vdisk and not just its access state.

Note that the preferred controller for accessing a Vdisk in an ALUA-capable array is defined in SCSI by the PREF bit, which is found in byte 0, bit 7 of the target port descriptor format⁷. If the PREF bit is set to one, this indicates that the Vdisk is preferred to the controller the target port group request was sent to; if it is set to zero, this indicates the Vdisk is not preferred to the controller the target port group request was sent to. Thus, the controller preference in an EVA array is equivalent to setting a Vdisk access path in Command View EVA to Path A/B-Failover/failback, as described in Vdisk provisioning.

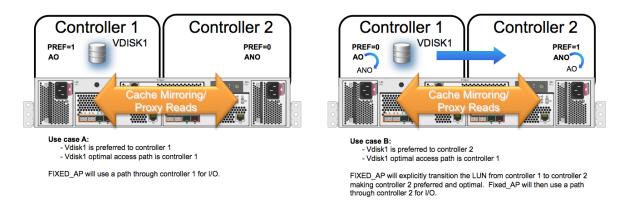

⁷ For more information, refer to SCSI Primary Commands (SPC) standard.

Primary use case

The primary use case for Fixed_AP is based on its ability to automatically return to a balanced, pre-configured environment after Vdisk access has become unbalanced following an event such as a controller failure or restore. After a controller failure, all Vdisks would migrate to the remaining controller and become optimized for that controller; however the logical unit's initial controller preference does not change and can point to the restored controller. Fixed_AP causes all Vdisks with a preference for the restored controller to migrate back to that controller.

Consider the uses cases shown in Figure 8.

Figure 8. Fixed_AP use cases.

Fixed_AP can cause explicit Vdisk transitions to occur and, in a poorly configured environment, may lead to Vdisk thrashing.

Since transitioning Vdisks under heavy loads can have a significant impact on I/O performance, the use of Fixed_AP is not recommended for normal production I/O with EVA arrays.

Note

Fixed_AP can only be used to explicitly transition Vdisks on storage systems that support explicit transitions, such as EVA arrays.

Fixed_AP can be leveraged to quickly rebalance preferred access to Vdisks after the configuration has become unbalanced by controller failure/restoration or implicit transitions triggered by the storage and others.

Summary

In vSphere 4.x/5.x, ALUA compliance and support for round robin I/O path policy have eliminated the intricate configuration required to implement multi-pathing in ESX 3.5 or earlier. These new features also help provide much better balance than you could achieve with MRU; furthermore, round robin policy allows I/Os to be queued to multiple controller ports on the EVA, helping create an instant performance boost.

Best practices for I/O path policy selection

- Round robin I/O path policy is the recommended setting for EVA asymmetric active-active arrays. MRU is also suitable if round robin is undesirable in a particular environment.
- Avoid using legacy Fixed I/O path policy with vSphere 4.x and EVA arrays.
- In general, avoid using Fixed_AP I/O path policy with vSphere 4.x and EVA. However, this policy can be leveraged to quickly rebalance Vdisks between controllers for example, after a controller has been restored following a failure. This use case can be employed with a single vSphere host when the array is not under heavy load. Once the balanced state has been restored, you should end the use of Fixed_AP and replace it with a recommended path policy.

 Avoid using Fixed I/O path policy with vSphere 5.x and EVA. However since Fixed I/O path policy in ESX 5.x is the same as Fixed_AP in ESX 4.1, the same use case considerations discussed above with ESX 4.1 also apply to Fixed I/O path policy in ESX 5.x.

Configuring multi-pathing

The multi-pathing framework for vSphere 4.x/5.x includes the following core components:

• Native Multi-pathing Plug-in (NMP)

Also known as the NMM (Native Multi-pathing management extension module (MEM))

• Storage Array Type Plug-in (SATP)

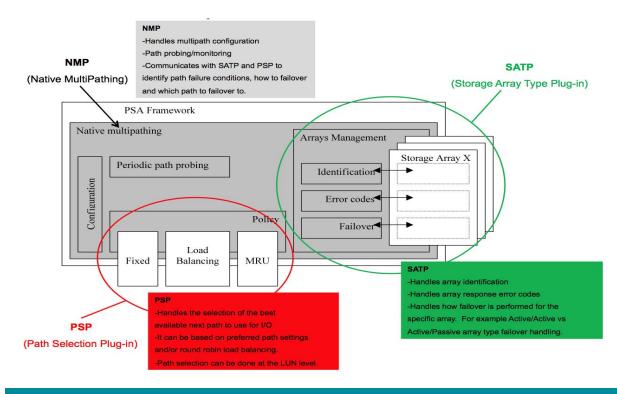

Also known as the SATM (Storage Array Type MEM); used in conjunction with the NMP

- Path Selection Plug-in (PSP)
 - Also known as the PSM (Path Selection MEM); used in conjunction with a specific SATP
- Multi-Pathing Plug-in (MPP)

Third-party implementation (which is outside the scope of this document) that takes the place of the NMP/SATP/PSP combination

Figure 9 outlines key components of the multi-pathing stack.

Figure 9. vSphere 4.x and 5.x multi-pathing stack

The key features of the multi-pathing plug-ins are as follows:

• SATP

The SATP is an array-specific plug-in that handles specific operations such as device discovery, the management of array-specific error codes, and failover.

For example, while storage arrays use a set of standard SCSI return codes to warn device drivers of various failure modes, they also make use of vendor-specific codes to handle proprietary functions and/or behavior. The SATP takes the appropriate action when these vendor-specific return codes are received.

PSP

The PSP selects an appropriate path to be used to queue I/O requests. PSP utilizes the following I/O path selection policies:

- Fixed
- Fixed_AP⁸
- MRU
- Round robin

PSP settings are applied on a per-Vdisk basis; thus, within the same array, it is possible to have some Vdisks using MRU while others are using the round robin policy.

NMP

The NMP ties together the functionality delivered by the SATP and PSP by handling many non-array specific activities, including:

- Periodical path probing and monitoring
- Building the multi-pathing configuration

When a path failure occurs, the NMP communicates with the SATP and PSP and then takes the appropriate action. For example, the NMP would update its list of available paths and communicate with the PSP to determine how I/O should be re-routed based on the specified path selection policy.

Displaying the SATP list

Although there is no way to monitor the NPM's list of available paths through vCenter, you are able to display a list of available SATPs and their respective default PSPs (as shown in Table 3).

Use the following CLI command on the ESX console:

esxcli nmp satp list/grep EVA

Note

Currently, you cannot reconfigure the SATP rules table through vCenter.

Table 3. vSphere 4.x and 5.x SATP rules table, with entries that are relevant to EVA arrays denoted by an asterisk

SATP	Default PSP	Description
VMW_SATP_ALUA_CX	VMW_PSP_FIXED	Supports EMC CLARiiON CX arrays that use ALUA
VMW_SATP_SVC	VMW_PSP_FIXED	Supports IBM SAN Volume Controller (SVC) appliances
VMW_SATP_MSA	VMW_PSP_MRU	Supports HP Modular Smart Array (MSA) arrays
VMW_SATP_EQL	VMW_PSP_FIXED	Supports EqualLogic arrays
VMW_SATP_INV	VMW_PSP_FIXED	Supports the EMC Invista application
VMW_SATP_SYMM	VMW_PSP_FIXED	Supports EMC Symmetrix arrays
VMW_SATP_LSI	VMW_PSP_MRU	Supports LSI and other arrays compatible with the SIS 6.10 in non- AVT mode
VMW_SATP_EVA*	VMW_PSP_FIXED	Supports HP EVA arrays

⁸ Only supported in vSphere 4.1

SATP	Default PSP	Description
VMW_SATP_DEFAULT_AP*	VMW_PSP_MRU	Supports non-specific active/passive arrays
VMW_SATP_CX	VMW_PSP_MRU	Supports EMC CLARiiON CX arrays that do not use ALUA protocol
VMW_SATP_ALUA*	VMW_PSP_MRU	Supports non-specific arrays that use the ALUA protocol
VMW_SATP_DEFAULT_AA	VMW_PSP_FIXED	Supports non-specific active/active arrays
VMW_SATP_LOCAL	VMW_PSP_FIXED	Supports direct-attached devices

IMPORTANT

SATPs are global, whereas a PSP can either be global or set on a per-Vdisk basis. Thus, a particular array can only use a specific SATP; however, Vdisks on this array may be using multiple PSPs – for example, one Vdisk can be set to round robin I/O path policy, while another Vdisk on the same array is set to MRU.

As indicated in Table 3, the following SATPs are relevant to EVA arrays:

- VMW_SATP_DEFAULT_AP This SATP is used by active/passive EVA arrays. However, since such arrays are not supported in vSphere 4.x and 5.x, you should not use this plug-in to enable a vSphere 4.x and 5.x connection to an active/passive EVA for production purposes.
- VMW_SATP_EVA This SATP is intended for active/active EVA arrays that have the Target Port Group Support (ALUA compliance) option turned off; however, all such arrays have TPGS turned on by default. Since this option is not user-configurable, no current EVA arrays use VMW_SATP_EVA.
- VMW_SATP_ALUA This SATP is intended for any ALUA-compliant array; thus, it is used with active-active EVA arrays.

Connecting to an active-active EVA array in vSphere 4.0, 4.1 and 5.x

When connecting a vSphere 4.x or 5.x host to an active-active EVA array, you should use the VMW_SATP_ALUA SATP as suggested above. This SATP is, by default, associated with VMW_PSP_MRU, a PSP that uses MRU I/O path policy.

There are two steps for connecting a vSphere 4.x and 5.x server to the EVA array:

- Change the default PSP for the VMW_SATP_ALUA from VMW_PSP_MRU to VMW_PSP_RR
- Update an advanced configuration parameter for the VMW_PSP_RR PSP

Changing the PSP

Firstly, you must change the VMW_SATP_ALUA default PSP/PSM from MRU to round robin.

PSPs in vSphere 4.x and 5.x are set at the Vdisk level and are based on an SATP. Since all active-active EVA arrays use the VMW_SATP_ALUA plug-in, configuring the VMW_SATP_ALUA default PSP to VMW_PSP_RR causes every new Vdisk from the EVA array to be configured automatically to use round robin path policy.

Make the change via the ESX CLI using the following command using ESX 4.x:

esxcli nmp satp setdefaultpsp -s VMW_SATP_ALUA -P VMW_PSP_RR

With ESXi 5.x, the esxcli command name space has changed. So to perform the same operation on ESXi 5.x as shown above for ESX 4.x, you must issue the following command:

esxcli storage nmp satp set -s VMW_SATP_ALUA -P VMW_PSP_RR

Note

When this setting is applied on the fly, it only affects new Vdisks added to the vSphere host. In order for the change to affect all Vdisks (including pre-existing logical units), a reboot of the host is recommended. Alternatively, you could unclaim and reclaim all devices managed by the NMP.

Best practice for changing the default PSP option in vSphere 4.x/5.x

For an EVA array environment, change the default PSP option for the VMW_SATP_ALUA SATP to VMW_PSP_RR.

On running systems where a reboot or unclaiming/reclaiming the devices is not feasible, the PSP setting can be changed on the fly for each Vdisk individually running the command below:

For ESX 4.x:
esxcli nmp device setpolicy -P VMW_PSP_RR -d naa.xxxxxxxx

For ESXi 5.x:

esxcli storage nmp device set -P VMW_PSP_RR -d naa.xxxxxxxx

Alternatively, the following scripts can be run to apply this setting to all your EVA Vdisks at once. Before running the scripts below, ensure that you only have EVA Vdisks connected to ESX or that setting Round Robin path policy to all SAN devices is your intended goal:

For ESX 4.x:

for i in 'esxcli nmp device list | grep ^naa.600' ; do esxcli nmp device setpolicy -P VMW_PSP_RR -d \$i; done

For ESXi 5.x:

for i in 'esxcli **storage** nmp device list | grep ^naa.600' ; do esxcli **storage** nmp **device set** -P VMW_PSP_RR -d \$i; done

Updating the new PSP

To optimize EVA array performance, HP recommends changing the default round robin load balancing IOPS value to 1. This update must be performed for every Vdisk using the following command on ESX 4.x:

esxcli nmp roundrobin setconfig -t iops -I 1 -d naa.xxxxxxxx

or the following command on ESXi 5.x

esxcli storage nmp psp roundrobin deviceconfig set -t iops -I 1 -d naa.xxxxxxxx

In an environment where you only have EVA Vdisks connected to vSphere 4.x/5.x hosts you can use the following script to automatically set I/O path policy for each Vdisk to round robin:

For ESX 4.x:

for i in 'esxcli nmp device list | grep ^naa.600' ; do esxcli nmp roundrobin setconfig -t iops -I 1 -d i; done

For ESXi 5.x:

for i in 'esxcli **storage** nmp device list | grep ^naa.600' ; do esxcli **storage** nmp **psp** roundrobin **deviceconfig set** -t iops -I 1 -d \$i; done

Note that all the Vdisks must previously be configured to use the Round Robin Path Policy before running the scripts above. Refer to <u>Changing the PSP</u> section above for instruction to change the PSP setting for the Vdisks.

For environments with multiple array models, merely change **grep naa.600** so that it matches the pattern to devices on the desired arrays only.

Caveats for connecting to vSphere 4.1 and 5.x

vSphere 4.0 does not provide a method for globally configuring the path selection plug-in (PSP or PSM) based on a particular array model. However, starting with vSphere 4.1, VMware introduced more granular SATP and PSP configuration options that allow array specific SATP and PSP configurations.

As in vSphere 4, each SATP has a default PSP. However, vSphere 4.1/5.x also gives you the ability to configure a particular PSP based on the storage array model. This is a significant improvement, allowing multiple arrays to use the same SATP but, by default, utilize different PSPs, which provides a tremendous savings in configuration time.

As in vSphere 4, the default PSP for VMW_SATP_ALUA in vSphere 4.1/5.x is VMW_PSP_MRU. Configuring the recommended PSP, VMW_PSP_RR, can be achieved in two different ways, depending on the deployment type:

• Same I/O path policy settings

If the vSphere 4.1/5.x cluster is connected to one or more ALUA-capable arrays using the same I/O path policy, you can change the default PSP for the VMW_SATP_ALUA to VMW_PSP_RR with the same steps described in the section <u>Connecting to an active-active EVA array in vSphere 4.0, 4.1 and 5.x</u> shown above.

Different I/O path policy settings

If the vSphere 4.1/5.x cluster is connected to two or more ALUA capable arrays that each requires different I/O path policy settings, you can leverage the new SATP and PSP configuration options in vSphere 4.1/5.x via the following command line:

For ESX 4.1:

```
esxcli nmp satp addrule -s VMW_SATP_ALUA -P VMW_PSP_RR -o iops -O iops=1 -c tpgs_on -V HP -M HSV300 -e "My custom EVA4400 rule"
```

For ESXi 5.x:

```
esxcli storage nmp satp rule add -s VMW_SATP_ALUA -P VMW_PSP_RR -o iops -O iops=1 - c tpgs on -V HP -M HSV300 -e "My custom EVA4400 rule"
```

This single command line achieves the following:

- Create a new rule in the SATP rule table for the array specified with -vendor and -model
- Set the default SATP for this array to VMW_SATP_ALUA
- Set the default PSP to VMW_PSP_RR
- Set the round robin option to IOPS=1

Repeat this command line for each ALUA-compliant array model to be shared by your vSphere 4.1/5.x cluster. With this single command line, you can achieve the same results as the two-stage configuration process required for vSphere 4. Thus, regardless of the deployment type in vSphere 4.1/5.x, running this single **addrule** command is far more efficient.

Use the following command to verify that the new rule has been successfully added:

esxcli nmp satp listrules

Deleting a manually-added rule

To delete a manually-added rule, use the **esxcli nmp satp deleterule** command; specify the same options used to create the rule. For example:

```
esxcli nmp satp deleterule --satp="VMW_SATP_ALUA" --psp="VMW_PSP_RR" --psp-
option="iops=1" --claim-option="tpgs_on" --vendor="HP" --model="HSV210" --
description="My custom HSV210 rule"
```

Caveats for changing the rules table

When making changes to the SATP rules table, consider the following:

• On-the-fly rule changes only apply to Vdisks added to the particular array after the rule was changed. Existing Vdisks retain their original settings until a vSphere server reboot occurs or a path reclaim is manually triggered.

- The array vendor and models strings used in the **addrule** command line must exactly match the strings returned by the particular array. Thus, if the new rule does not claim your devices even after a server reboot then verify that the vendor and model strings are correct.
- As you add rules to the SATP rules, tracking them can become cumbersome; thus, it is important to always create a rule with a very descriptive, consistent description field. This facilitates the retrieval of user-added rules using a simple filter.

Best practice for changing the default PSP in vSphere 4.1/5.x

• Create a new SATP rule for each array model.

Best practice for configuring round robin parameters in vSphere 4.x/5.x

• Configure IOPS=1 for round robin I/O path policy.

Caveats for multi-pathing in vSphere 4.x/5.x

This section outlines caveats for multi-pathing in vSphere 4.x associated with the following:

- Deploying a multi-vendor SAN
- Using Microsoft clustering
- Toggling I/O path policy options
- Using data replication (DR) groups
- Using third-party multi-pathing plug-ins

Deploying a multi-vendor SAN

In an environment where ALUA-capable arrays from multiple vendors are connected to the same vSphere 4.x cluster, exercise caution when setting the default PSP for VMW_SATP_ALUA, especially if the arrays have different recommendations for the default PSP option.

Setting the appropriate PSP differs depending on the deployment type.

vSphere 4 deployment

If the total number of EVA Vdisks is smaller than the total number of logical units from third-party arrays, then set the default PSP option to VMW_PSP_RR, assuming that the third-party storage vendor(s) also recommend(s) this setting. Otherwise, use the recommended default for the third-party arrays and manually configure EVA Vdisks. Thus, to minimize configuration time, the bulk of the task is automatically performed by default using vSphere 4.x, leaving you to manually run a simple script to set the desired PSP – VMW_PSP_RR – for EVA Vdisks.

The above recommendation only applies to the following use case:

- The EVA and third-party arrays are in the same vSphere 4 SAN
- Arrays from two or more vendors are ALUA-compliant
- There are different default recommendations for PSPs

vSphere 4.1/5.x deployment

• If the multi-vendor SAN is being shared by a vSphere 4.1 cluster, then create a new SATP rule entry for each array, setting the configuration parameters as recommended by the particular vendor.

Best practice for configuring PSP in a multi-vendor SAN

- **vSphere 4**: When using vSphere 4 in a multi-vendor, ALUA-compliant SAN environment, configure the default PSP for the VMW_SATP_ALUA SATP to the recommended setting for the predominant array type or to the recommended setting for the array type with the most Vdisks provisioned for vSphere access.
- vSphere 4.1/5.x: Create a SATP rule entry for each storage array with the desired attributes.

Using Microsoft clustering

At the time of writing, VMware does not support round robin I/O path policy in conjunction with VMs clustered via Microsoft Cluster Server (MSCS). Thus, HP recommends setting all VMware Raw Device Mapping (RDM) Vdisks used by an MSCS cluster to utilize MRU as the preferred I/O path policy.

Since most MSCS cluster deployments utilize several logical units, you should configure the path policy for these Vdisks manually.

Best practice for configuring MSCS cluster Vdisks

• MSCS cluster Vdisks should be configured to use the MRU I/O path policy. Since the recommended default setting for all EVA Vdisks is round robin, you must manually configure these Vdisks to MRU.

Toggling I/O path policy options

Once configured, avoid toggling the I/O path policy for Vdisks using round robin policy. When I/O path policy is changed from round robin to any other (fixed or MRU), either through vCenter or a CLI, all round robin advanced configuration settings are lost. The next time you set round robin policy for that device, you must manually reset these settings.

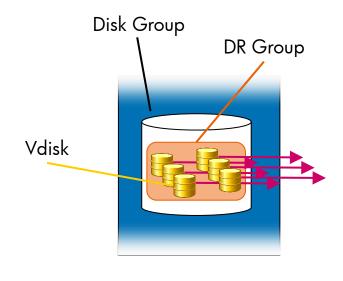

Using data replication groups

The HP Continuous Access EVA software allows data to be replicated between two or more EVA arrays, either synchronously or asynchronously.

Continuous Access EVA supports various interconnection technologies such as Fibre Channel or Fibre Channel over IP (FCIP).

A DR group is the largest replication object within Continuous Access EVA and is comprised of replicated Vdisks (copy sets), as shown in Figure 10.

Figure 10. Relationship between Vdisks and the DR group

Just like a Vdisk, a DR group is managed through one controller or the other; in turn, this controller must manage all Vdisks within the particular DR group. Thus, when a Vdisk is added to an existing DR group, its optimal controller is the one currently managing the DR group.

Since the inheritance of controllers can impact the overall balance of Vdisk access, you should ensure that DR groups are spread across both controllers.

Best practice for managing controllers for DR groups

• Ensure that DR groups are spread between the controllers so as to maintain an adequate balance.

Using third-party multi-pathing plug-ins (MPPs)

vSphere 4.x/5x allow third-party storage vendors to develop proprietary PSP, SATP, or MPP plug-ins (or MEMs).

These third-party MEMs are offered to customers at an incremental license cost and also require enterprise VMware licensing.

The EVA array was designed to provide optimal performance and functionality using native VMware multi-pathing plug-ins, saving you the extra work and expense associated with proprietary plug-ins. When used, configured and tuned appropriately, native plug-ins can significantly reduce configuration time and provide enhanced performance in most environments at zero incremental cost, while keeping the solution simplified.

Upgrading EVA microcode

An online upgrade of EVA microcode is supported with vSphere 4.x/5.x.

When performing such upgrades it is critical to follow the general EVA Online Firmware Upgrade (OLFU) guidelines defined in the OLFU best practices guide⁹.

From a vSphere 4.x/5x perspective, VMs using RDM Vdisks are more susceptible to issues resulting from an OLFU. It is important to ensure that the SCSI disk timeout for all VMs is set to a minimum of 60 seconds, or higher (60 – 90 seconds) in a larger environment.

Guidelines are provided for setting the SCSI disk timeout for Microsoft Windows and Linux VMs.

Setting the timeout for Windows VM

For a VM running Windows Server 2003¹⁰ or earlier, change the value of the HKEY_LOCAL_MACHINE/SYSTEM/CurrentControlSet/Services/Disk/TimeoutValue registry setting to **3c** (that is, **60** expressed in hexadecimal form).

A reboot is required for this change to take effect.

Setting the timeout for Linux VMs

Use one of the following commands to verify that the SCSI disk timeout has been set to a minimum of 60 seconds:

cat /sys/bus/scsi/devices/W:X:Y:Z/timeout

or

cat /sys/block/sdX/device/timeout

If required, set the value to **60** using one of the following commands:

```
echo 60 > /sys/bus/scsi/devices/W:X:Y:Z
```

or

```
echo 60 | cat /sys/block/sdX/device/timeout
```

where W:X:Y:Z or sdX is the desired device.

No reboot is required for these changes to take effect.

⁹ See <u>http://h20000.www2.hp.com/bc/docs/support/SupportManual/c01921588/c01921588.pdf</u>

¹⁰ In Windows Server 2008, the SCSI timeout defaults to 60 seconds.

Overview of vSphere 4.x/5x storage

vSphere 4.x/5x support VMware Virtual Machine File System (VMFS), RDM, and Network File System (NFS) datastores, each of which can deliver benefits in a particular environment. This section provides information for the following topics:

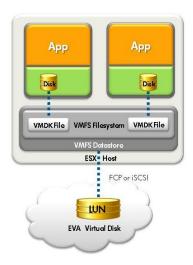

- Using VMFS
- Using RDM
- Comparing supported features
- Implementing a naming convention
- Sizing the vSphere cluster
- Aligning partitions

Using VMFS

VMFS is a high-performance cluster file system designed to eliminate single points of failure, while balancing storage resources. This file system allows multiple vSphere 4.x hosts to concurrently access a single VMDK (Virtual Machine Disk Format), as shown in Figure 11.

VMFS supports Fibre Channel SAN, iSCSI SAN, and NAS storage arrays.

Figure 11. VMFS datastore

Best practices for deploying VMFS

- To avoid spanning VMFS volumes, configure one VMFS volume per logical unit.
- In general limit VMs or VMDKs to 15-20 per volume.
- Either place I/O-intensive VMs on their own SAN volumes or use RDMs, which can minimize disk contention.
- When placing I/O-intensive VMs on a datastore, start with no more than six to eight vSphere hosts per datastore. Monitor performance on the vSphere hosts to ensure there is sufficient bandwidth to meet your application requirements and that latency is acceptable.

Using RDM

As shown in Figure 12, RDM allows VMs to have direct access to Vdisks, providing support for applications such as MSCS clustering or third-party storage management.

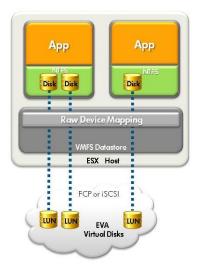

vSphere 4.x/5.x provides the following RDM modes, which support advanced VMware features like vMotion, High Availability (HA), and Distributed Resource Scheduler (DRS):

- Virtual compatibility mode (vRDM):
 - All I/O travels through the VMFS layer
 - RDMs can be part of a VMware snapshot
- Physical compatibility mode (pRDM):
 - All I/O passes directly through the underlying device
 - pRDM requires the guest to use the virtual LSI Logic SAS controller
 - pRDM is most commonly used when configuring MSCS clustering

There are some limitations when using RDM in conjunction with MSCS or VMware snapshots – for example, when configuring an MSCS cluster between a physical Windows Server and a Windows virtual machine, you should utilize pRDM because vRDM is not supported in that configuration. However, for a cluster between Windows Virtual Machine residing on the same host (aka cluster in a box) you can use both vRDM and pRDM for the cluster configuration. Note that when configuring Windows 2008 VMs in a cluster, you must use the LSISAS Virtual adapter for the shared pRDM.

For more information, refer to the VMware white paper, "Setup for Failover Clustering and Microsoft Cluster Service."

Figure 12. RDM datastore

Comparing supported features

Table 4 compares features supported by VMFS and RDM datastores.

Table 4. Datastore supported features

Feature	VMFS	RDM
VMware Native Multi-pathing (NMP)	Yes	Yes
VMware vMotion	Yes	Yes
VMware Storage vMotion	Yes	Yes
VMware FT	Yes	Yes
VMware sDRS	Yes	No
VMware SIOC	Yes	No
MSCS	Yes ¹¹	Yes

Implementing a naming convention

When working with multiple datastores, VMDKs, and RDMs in conjunction with large clusters or SANs, management can become complex. Unless you use a suitable naming convention, it may be very difficult to locate a particular datastore for management or troubleshooting purposes.

For example, array model names should not be included in the naming convention – if you move a Vdisk from one EVA model (such as the EVA8100) to another (such as the EVA4400), the naming convention would break down. You should not include the Vdisk number in a datastore or RDM naming convention because the number for a Vdisk in Datacenter A may not be maintained when the Vdisk is replicated and presented to a host in Datacenter B. Similarly, you should not include Vdisk size in a naming convention because it is probable that this size will change.

To avoid confusion, you need detailed documentation on each array, datastore, Worldwide Name (WWN), and host name. In addition, avoid using the following in the name for a datastore or RDM:

- EVA model or controller name
- EVA WWN (or any part thereof)
- Vdisk number
- Vdisk size
- Vdisk WWN
- Name of the vSphere server name from which the datastore was created

Creating the convention

HP recommends naming VMFS datastores and RDMs in vCenter with the same name used when creating the Vdisk in Command View EVA or when using SSSU scripting tools. While this approach is beneficial, it may require some coordination with the storage administrator.

Note

When creating Vdisks in Command View or SSSU, Vdisk names are unique to the particular array.

¹¹ Only supported with vRDM using VMs in a cluster within a box configuration.

In a vSphere cluster, ESX prevents you from creating datastores with the same name, regardless of the array they are created on. This capability yields an environment where datastore names are unique across the entire infrastructure, while RDM names are unique to the particular vSphere host – or, depending on your choice of names, to the entire infrastructure.

Using descriptive naming

When creating Vdisks in Command View EVA, HP recommends using descriptive naming for the datastore. For example, a suitable naming convention might be as follows:

<Location>_<Location Attribute>_<Department>_<Vdisk Type>_<Usage>_#

Table 5 outlines the various components of this naming convention.

Table 5. Sample na	ming convention
--------------------	-----------------

Component	Description	Example
<location></location>	Geographical location of the team, group or division for which the storage is being allocated	The location could be a city, state, country, or a combination thereof.
<location attribute=""></location>	Specific attribute of the particular location, such as an office building floor or the scope of the department	• Building R5 • Third floor
<department></department>	Job function of the team, group or division for which the storage is being allocated	• IT • Sales • Finance
<vdisk type=""></vdisk>	Type of Vdisk	 RDM VMFS (datastore)
<usage></usage>	How the Vdisk will be used	 VM boot Exchange logs Exchange data Oracle_archLogs Oracle_data
<#>	Provides enumeration in the event that multiple disks with the same name should be needed	• 1 • 0002

The following are examples of this sample naming convention:

- Houston_Enterprise_Sales_VMFS_VMBoot_1
- Houston_Enterprise_Sales_VMFS_VMBoot_2
- LA_Corporate_IT_RDM_ExchLogs_1
- LA_Corporate_IT_RDM_ExchLogs_2

The advantages of this naming convention are as follows:

- Simple
- Synchronizes EVA and vSphere naming
- Independent of any unique array or Vdisk properties
- Does not break due to replication or Storage vMotion
- Uniqueness automatically ensured by EVA

However, there are challenges associated with the naming convention, including the following:

- Inability to quickly match the array Vdisk number only using the Vdisk name
- Cross-reference matrix required for information such as Vdisk ID and array

Both of the above challenges can be addressed by deploying the HP Insight Control Storage Module for vCenter plug-in.

Best practice for naming datastores

- When naming a datastore, utilize the same name used in Command View when the Vdisk was created.
- Use simple, consistent names for your datastores in the future, you may need to add vSphere hosts to the cluster.

Sizing the vSphere cluster

Knowing how many vSphere hosts can be supported per Vdisk will enhance your ability to manage the cluster¹².

Monitor resource utilization to recognize VMs that are I/O-intensive. Often, high I/O requirements will lower your overall host count.

Best practice for using Vdisk IDs

• To make it easier to manage the cluster and SAN, use the same Vdisk ID for all vSphere hosts in the same cluster.

Aligning partitions

In a vSphere environment, partitions on VM data disks must be aligned with disks on the EVA array; however, the EVA array has no alignment requirements. See the <u>VMware vStorage API for Array Integration</u> section below for VAAI specific alignment considerations and best practices.

Aligning Vdisk and VMFS partitions

The array is a virtualized storage system that is managed by Command View. When you use Command View to create a Vdisk to present to a supported host, the host mode you specify ensures that the Vdisk is appropriately aligned for the file system you plan to mount.

When you present a Vdisk to a host, you can use your favorite secure shell (ssh) client to login to your vSphere host and view the configuration of the presented Vdisk; you can then format the Vdisk with a VMFS filesystem. Using the vSphere client to create the VMFS filesystem automatically aligns the VMFS filesystem partition with the underlying Vdisk.

Aligning VM operating system partitions

IMPORTANT

If you are using Microsoft Windows Vista®, Windows 7, or Windows Server 2008, you do not need to align partitions. These operating systems correctly align the partition at the time you create the VMDK.

At some stage of your deployment, you may need to align the partitions for certain VM operating systems with the VMDK to avoid performance degradation in your VM or application.

For EVA arrays, HP recommends creating all your VMDK files via the vSphere client and verifying that each Vdisk is appropriately aligned; other storage systems may be different.

If you are using Storage vMotion to move your datastores, consult the appropriate storage vendor to ensure your VMFS partitions or VMDK files are correctly aligned to disk.

¹²The maximum number of Vdisks that can be connected to a vSphere cluster is 256.

VMware has carried out testing to compare I/O performance with aligned and non-aligned file systems and, as a result, suggests working with your vendor to establish the appropriate starting boundary block size. For more information, refer to the VMware white paper, "<u>Performance Best Practices for VMware vSphere 4.0</u>."

Best practices for aligning the file system

- No alignment is required with Windows Vista, Windows 7, or Windows Server 2008.
- Use the vSphere client when creating your datastore, which correctly aligns the file system.
- Verify that VMDKs used by the guest operating system are correctly aligned.

Enhancing storage performance

A range of vSphere 4.x/5.x features and tuning options provide opportunities for enhancing storage performance. This section provides information on the following topics:

- Optimizing queue depth
- Using adaptive queuing
- Using the paravirtualized virtual SCSI driver
- Monitoring EVA performance in order to balance throughput
- Optimizing I/O size

Optimizing queue depth

Queue depth is a function of how quickly processes are loaded into the queue and how fast the queue is emptied between the HBA and a Vdisk.

Tuning the Vdisk queue depth is often regarded as a requirement in a vSphere environment that uses SAN storage. Indeed, in some deployments, tuning the queue may help to enhance performance; however, injudicious tuning can result in increased latency. HP suggests that, if your storage system is properly configured and balanced, default queue depth values may be ideal. The best approach is to analyze the entire environment, not just a single vSphere host.

Adjusting the queue depth requires you to determine how many commands the HBA can accept and process for a given logical unit. Thus, as a best practice when adjusting the HBA queue depth, you should adjust the vSphere **Disk.Sched.NumReqOutstanding** setting for each vSphere host. The simplest way is to use the vSphere client and login to vCenter to make the necessary adjustments.

For more information on changing the HBA queue depth with vSphere 4.x, refer to the VMware guide, "<u>Fibre</u> <u>Channel SAN Configuration Guide</u>."

Best practice for adjusting the queue depth

• When increasing the HBA queue depth, also increase the vSphere Disk.Sched.NumReqOutstanding setting.

Using adaptive queuing

ESX 3.5 and vSphere 4.x/5.x provide an adaptive queue depth algorithm that can dynamically adjust the logical unit (LU) queue depth in the VMkernel I/O stack when congestion is reported by the storage system in the form of QUEUE FULL or DEVICE BUSY status.

Dynamically adjusting the LU queue depth allows the VMkernel to throttle back I/O requests sent to the particular LU, thus reducing I/O congestion in the storage system.

Adaptive queuing is controlled by the following advanced parameters:

- **QFullSampleSize**: Controls how quickly the VMkernel should reduce the queue depth for the LU returning DEVICE BUSY/QUEUE FULL status; by default, QFullSampleSize is set to **0**, which disables adaptive queuing
- QFullThreshold: Controls how quickly the queue depth should be restored once congestion has been addressed

vSphere administrators often enable adaptive queuing as a means to address storage congestion issues. However, while this approach can temporarily help reduce storage congestion, it does not address the root cause of the congestion. Moreover, although adaptive queuing can enhance performance during times when storage is congested, overall I/O performance is superior in a well-tuned, balanced configuration.

Before enabling adaptive queuing, HP highly recommends examining your environment to determine the root cause of transient or permanent I/O congestion. For well-understood, transient conditions, adaptive queuing may help you accommodate these transients at a small performance cost. However, to address more permanent I/O congestion, HP offers the following suggestions:

- Using VMware disk shares
- Using VMware Storage IO Control (SIOC)
- Re-evaluating the overall ability of the storage configuration to accommodate the required workload for example, non-vSphere hosts may have been added to a well-tuned, balanced SAN, placing additional stress on the shared storage; such configuration changes must be investigated and addressed before you throttle back the vSphere hosts.

If you must enable adaptive queuing, HP recommends the following values for HP EVA Storage homogeneous environments:

- QFullSampleSize = 32
- QFullThreshold = 4

For environment where the ESX servers are connected to both HP 3PAR Storage and HP EVA Storage, then the following values are recommended:

- QFullSampleSize = 32
- QFullThreshold = 8

Best practices for adaptive queuing

- Rather than enabling adaptive queuing, determine the root cause of the I/O congestion.
- If you decide to use adaptive queuing in an homogenous HP EVA Storage environment, set the values as follows: **QFullSampleSize** = **32** and **QFullThreshold** = **4**.

Using the paravirtualized virtual SCSI driver

First available in vSphere 4 the VMware paravirtualized virtual SCSI (pvSCSI) driver is installed with the VMware Tools. This guest OS driver communicates directly with VMware Virtual Machine Monitor, helping to increase throughput while reducing latency.

In testing, the pvSCSI driver has been shown to increase the performance of Vdisks compared to standard virtual SCSI adapters such as LSILogic and BusLogic.

When using lometer, for example, there was a performance improvement of between 10% – 40%, depending on the workload used. The tested I/O block sizes were 4 KB, 8 KB, and 64 KB for sequential and random I/O workloads.

Best practices for improving the performance of VMs with I/O-intensive workloads

 Consider using the pvSCSI driver with the VM's data logical units, which can enhance performance by 10% – 40%, depending on the particular workload used.

Monitoring EVA performance in order to balance throughput

ALUA compliance in vSphere 4.x has significantly reduced configuration complexity and given you the ability to quickly configure a balanced Vdisk environment. However, you should monitor EVA host port performance to ensure that this configuration is also balanced from the perspective of I/O throughput.

Even though Vdisk access may be well-balanced between the two controllers in a particular configuration, it is possible that most or all I/O requests are going to Vdisks on just one of these controllers. In this scenario, the resources of one of the controllers are not being fully utilized. For example, Figure 13 shows an environment where the majority of I/O throughput is routed through a single controller despite the environment being balanced from the perspective of Vdisk access. Each port on Controller 2 is processing 300 MB/s of I/O throughput, while ports on Controller 1 are only processing 20 MB/s each.

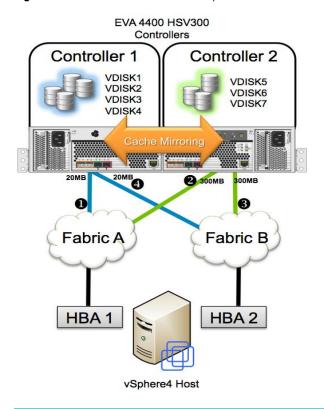

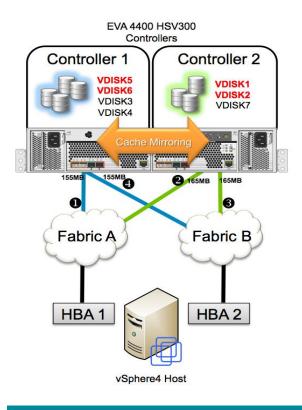

Figure 13. Unbalanced I/O access in a vSphere 4.x environment

Better balanced throughput could be achieved in this example by moving one or more of the Vdisks on Controller 2 (Vdisk5, 6 or 7) to Controller 1. Simply update the Vdisk controller access preference within Command View EVA to the desired value; alternatively, if you need to move multiple Vdisks to an alternate controller, you could use SSSU scripting tools.

Within a few minutes of the update, vSphere 4.x will switch the I/O access path of the Vdisk to the new controller, resulting in better balanced I/O accesses that may, in turn, lead to improved I/O response times.

Figure 14 shows a better-balanced environment, achieved by moving the controller ownerships of Vdisk 5 and 6 to Controller 1 and of Vdisk1 and 2 to Controller 2.

Figure 14. Balanced I/O access in a vSphere 4.x environment after changing controller ownership for certain Vdisks

This type of tuning can be useful in most environments, helping you achieve the optimal configuration.

Monitoring EVA host port throughput

In order to achieve the balance described above, you must be able to monitor EVA host port throughput. HP recommends using EVAperf, a utility that is bundled with Command View EVA management software and can be accessed from the desktop of the Command View EVA management station.

For more information on using EVAperf to monitor host port throughput, refer to <u>Appendix C – Balancing I/O</u> throughput between controllers.

Best practice for monitoring EVA host port throughput

• To allow you to make proactive adjustments, use EVAperf to monitor EVA performance.

Optimizing I/O size

You can enhance the performance of applications that generate large I/Os by reducing the maximum I/O size that vSphere hosts can send to the EVA array.

By design, vSphere 4.x allows I/Os as large as 32 MB to be sent to the array. You can control I/O size via the vSphere advanced parameter **Disk.DiskMaxIOSize**. HP recommends setting this value to **128 KB** for an EVA array to optimize overall I/O performance.

Note VMware makes a similar recommendation in their <u>knowledge base article</u> 1003469.

Best practice for improving the performance of VMs that generate large I/Os

• Consider setting the vSphere advanced parameter Disk.DiskMaxIOSize to 128 KB to enhance storage performance.

VMware vStorage API for Array Integration (VAAI)

Starting with firmware 10100000, the HP EVA Storage arrays now support VMware VAAI. VMware VAAI provides storage vendors access to a specific set of VMware Storage APIs, which enable offloading specific I/O and VM management operations to the storage array. With hardware offload, an administrator is able to reduce memory and CPU consumption on VAAI enabled ESX/ESXi hosts, reduce storage array port and fabric I/O traffic, and significantly increase performance and scalability of the configuration.

VMware VAAI storage integration is made possible by leveraging specific primitives within the API. Each of the primitives enables hardware offload of a specific capability. The following table summarizes the VAAI primitives support by HP EVA Storage

Primitive	Equivalent Name	ESX 4.1/ESXi 4.1	ESXi 5.x
Full Copy/Hardware Assisted Move	XCOPY	YES	YES
Block Zeroing/Hardware Assisted Zeroing	WRITE SAME	YES	YES
Hardware Assisted Locking	ATS	YES	YES
Out of Space Awareness	TP Stun (VM Pause)	YES	YES
Thin Provisioning			
Thin Provisioning Reporting	TP CAPABILITY	NA	YES
Soft Threshold Monitoring	NA	NA	YES
Hard Threshold Monitoring	NA	NA	YES
Space Reclamation	UNMAP	NA	NO
ESX VAAI Software Plugin required	NA	YES	NO

Table 6. VAAI Primitives support

Table 6 summarizes VAAI primitives supported with HP EVA Storage for ESX/ESXi 4.1 and ESXi 5. A few important things to note from this summary are:

VAAI Support

VMware only supports VAAI on ESXi/ESX 4.1 and ESXi 5. ESX/ESXi 4.0 is not supported. Customers using vSphere 4 will need to upgrade to vSphere 4.1 at minimum to benefit from VAAI offload acceleration. It is recommended to upgrade to ESXi 5.x in order to leverage a much simpler VAAI configuration, because ESXi 5 does not require a VAAI software plugin.

VAAI Software Plugin

Each storage vendor provides a VAAI software plugin for their respective arrays. A VAAI plugin is required when using ESX/ESXi 4.1. Some arrays have this software plugin built into ESX and require no asynchronous installation. The HP EVA Storage VAAI plugin is a software plugin that must be asynchronously downloaded and installed on ESX/ESXi 4.1. Note that for HP EVA Storage arrays, a VAAI software plugin is not required for ESXi 5.x.

Thin Provisioning

Thin Provisioning support was introduced with ESXi 5 and is not supported on ESX/ESXi 4.1

• TP STUN (VM Pause)

Despite ESX/ESXi 4.1 not supporting any of the Thin Provisioning features, ESX/ESXi 4.1 does support the ability to pause a VM, on detection of an out of space condition.

• Plugin-less deployment

The HP EVA Storage firmware 10100000 VAAI implementation is SCSI standards based which is directly compatible with the standards based implementation of VAAI in ESXi 5. Therefore, no VAAI software plugin is required when using ESXi 5 with HP EVA Storage VAAI enabled.

In this paper we will not explain what each primitive does because that subject has been abundantly discussed in other HP EVA Storage documentation such as the HP EVA Storage array release notes. On the other hand, the paper will focus the discussion on important caveats to take into considerations when deploying VAAI with HP EVA Storage while highlighting recommended VAAI deployment best practices

VAAI alignment considerations

Starting with ESXi 5, VMware VMFS partitions created with ESXi 5 are aligned on 1MB boundary of the underlying logical unit address space presented from storage. Therefore, all VMDKs carved from VMFS volumes are also aligned on 1MB boundaries.

On the other hand, on ESX 4.1, VMFS partitions are 64KiB aligned and VMDKs carved from these VMFS volumes in turn are 64KiB aligned. When an ESX/ESXi 4.1 host is upgraded to ESXi 5, datastores that were created under ESX/ESXi 4.1 will retain the alignment they were created with.

Because VAAI WRITE SAME and XCOPY operations are performed respectively to initialize or clone VMDKs, these operations conform to the alignment of the VMFS partition address space. When deploying HP EVA Storage VAAI solutions, VMFS partitions to be used for VAAI acceleration must be 64KiB or 1MB aligned.

Datastore that are not 64KiB or 1MB aligned will not be able to leverage VAAI acceleration benefits and will revert back to using legacy ESX data movers to perform clone and zeroing operations. For this reason, when planning to deploy VAAI with HP EVA Storage, datastores that do not meet this alignment recommendation need to be re-aligned to 64KiB or 1MB alignment. In some cases this may require evicting all the VMs from this datastore, then deleting and recreating the datastore with the desired alignment.

Best practice for aligning VMFS volume for use with HP EVA Storage VAAI

• VMFS datastore must be aligned to either 64KIB or 1MB boundary for use with HP EVA Storage VAAI integration.

VAAI transfer size consideration

VAAI WRITE SAME requests on ESX 4.1 and ESXi 5.x have a default transfer size of 1MB whereas XCOPY requests default to a 4MB transfer size (tunable to as much as 16MB). For maximum performance of VAAI offloading operations to storage, the HP EVA Storage has been optimized for XCOPY and WRITE SAME request that are multiples of 1MB. Transfer sizes that are non-multiple of 1MB, will revert to utilizing ESX legacy data movers. Furthermore, note that VMware VAAI does not support clone operations between datastores of different block sizes. So when using ESX 4.1 with EVA, it is important to ensure that the datastores that are used for VAAI clone operations are either 64k or 1MB aligned and that they are also of the same block size.

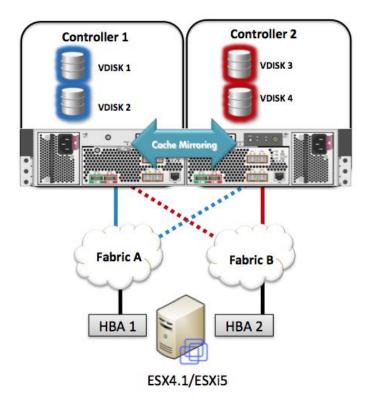

VAAI and EVA proxy operations considerations

As discussed earlier in this paper, HP EVA Storage arrays are asymmetric active-active arrays and ALUA compliant. In this architecture, a logical unit can be accessed through both controllers of the EVA. However, one of the two controllers is an optimal (often referred to as preferred) path to the logical unit. VAAI WRITE SAME and XCOPY primitives will adhere to these controller preference rules as follows:

- WRITE SAME commands to a logical unit will be sent to the controller that is the optimal path to the logical unit.
- XCOPY commands copy data from one logical unit to another (where source and destination are allowed to be the same). During XCOPY operations, XCOPY commands are sent to the controller that owns the destination logical unit.

Figure 15 below illustrate an HP EVA Storage configuration where controller 1 owns Vdisks 1 and 2 and controller 2 owns Vdisks 3 and 4.

In this configuration, access to the Vdisks by VAAI WRITE SAME and XCOPY commands is summarized in the table below:

Iable 7. VAAI com	nand controller access	
Command	Operation	Controller Receiving Command
WRITE SAME	Zero addresses on Vdisk1 or Vdisk2	Controller 1
WRITE SAME	Zero addresses on Vdisk3 or Vdisk4	Controller 2
XCOPY	Copy data from Vdisk1 to Vdisk1	Controller 1
XCOPY	Copy data from Vdisk1 to Vdisk2	Controller 1
XCOPY	Copy data from Vdisk1 to Vdisk3 or Vdisk4	Controller 2
XCOPY	Copy data from Vdisk3 to Vdisk3	Controller 2

Copy data from Vdisk3 to Vdisk4

Copy data from Vdisk3 to Vdisk1 or Vdisk2

Table 7.	VAAI	command	controller	access
----------	------	---------	------------	--------

XCOPY

XCOPY

From the summary in Table 7, we can see that WRITE SAME operations are sent to the optimal "owning" controller for a Vdisk. So when zeroing multiple Vdisks concurrently, there is a significant performance advantage of zeroing Vdisks owned by different controllers concurrently over Vdisks that are owned by the same controller.

Controller 2

Controller 1

Similarly, during XCOPY operations, EVA controllers work together to transfer the data from the source Vdisk to the destination Vdisk using the controller proxy link when the source and destination Vdisks are on different controllers. Hence for improved performance it is best to perform XCOPY operations between Vdisks that are owned by different controllers.

Best practice for zeroing

• For improved performance, when performing zeroing activities on two or more Vdisks concurrently, it is best to have the Vdisks ownership evenly spread across controllers.

Best practice for XCOPY

- XCOPY operations can benefit from increased performance when different EVA controllers own the source and destination datastores.
- When an HP EVA Storage array is in degraded mode, such as when one of the two controllers is down, the proxy relationship between the two controllers will also be affected. Under this condition, only the remaining controller will process all XCOPY and zeroing operations in addition to servicing non-VAAI I/Os. Therefore, when the EVA is in a degraded mode, VAAI operations should be avoided.

Best practice for degraded EVA

• When the EVA is in degraded mode, avoid using VAAI operations.

VAAI and Business Copy and Continuous Access

HP EVA Storage local and remote replication of a Vdisk generates additional workloads for the disk groups servicing this Vdisk. The EVA VAAI implementation has carefully taken into consideration the tradeoffs that exist between speeding up VAAI workloads versus equally servicing other important non-VAAI workloads without performance impact. Therefore, when using VAAI primitives on a Vdisk that is in a Business Copy or Continuous Access relationship, administrators should expect throttled VAAI performance gains.

Best practice for Business Copy and Continuous Access

• When using VAAI on Vdisks that are in snapshot, snapclone, mirror clone, or continuous access relationships VAAI performance may be throttled.

VAAI operation concurrency

HP EVA Storage will allow VAAI cloning and zeroing operations or any combination of them to be performed concurrently and in parallel to other VAAI and non-VAAI operations. However, as previously discussed, the HP EVA Storage array VAAI implementation was also carefully designed to only allow VAAI operation a finite amount of system resources in order to reduce the performance impact on external and internal non-VAAI I/O workloads. This is a design choice that guarantees that VAAI clone/zeroing operations adequately share storage array resources and bandwidth.

Following the VAAI best practices discussed in this guide will provide the best performance to VAAI clone and zeroing operations while maintaining adequate I/O latencies and throughput for VAAI and non-VAAI workloads.

VAAI clone and zeroing operations offer the benefit of increased performance to VM cloning, VM template creation and VM initialization. However, queuing multiple concurrent such operations may induce undesired latency to the overall system affecting the performance of VAAI and non-VAAI workloads. Therefore, it is best to keep the number of concurrent VAAI operations to a minimum, which will help keep VAAI performance high and lower the performance impact on non-VAAI workloads.

Best practice for concurrent VAAI operations

- Minimize the number of concurrent VAAI clone and/or zeroing operations to reduce the impact on overall system
 performance.
- An inadequate number of physical disk spindles in a disk array can bottleneck the performance of any disk subsystem despite cache sizes, controller count or speed. To benefit from the performance advantages of VAAI and concurrent VAAI operations, it is critical that the deployed HP EVA Storage array is configured with an adequate minimum number of hard drives. The following table provides minimum estimates for the number of drives needed

to achieve adequate VAAI copy rates with Vraid5 Vdisks. Note that these estimates are dependent on the overall I/O workload of the system.

Table 8. VAAI command controller access

HP EVA Storage	7.2K RPM HDD	10K RPM HDD	15K RPM HDD
EVA4400	13	65	55
EVA6400	110	60	45
EVA8400	110	60	45
P6300	140	75	55
P6500	175	90	65

Best practice for minimum drive requirements for VAAI

• Ensure the HP EVA Storage is configured with an adequate number of drives when using VAAI. Refer to Table 8 for guidance.

Summary of best practices

How can I best configure my storage?

- To size an EVA disk group, start by understanding the characteristics of the application's workload to ensure the virtualized environment is capable of delivering sufficient performance.
- Using a single EVA disk group is typically sufficient to satisfy all your storage optimization objectives (cost, performance, and capacity).
- Fill the EVA with as many disks as possible, using the largest, equal-capacity disks.
- The single-drive protection level should be sufficient for your disk group unless MTTR is longer than seven days.
- Do not use Vraid6 unless absolutely necessary. Vraid5 is less expensive and provides adequate redundancy for a vSphere 4.x deployment.
- When using disks with differing performance characteristics, use a single disk group rather than multiple disk groups, having disks with the same characteristics.
- Alternate controller ownership for EVA Vdisks between Controller A and Controller B using the Path-A-Failover/Failback or Path-B-Failover/Failback setting.
- Ensure that the managing controllers for DR groups are spread between Controller A and Controller B to maintain an adequate balance in the system configuration.

Which is the best I/O path policy to use for my storage?

• Round robin I/O path policy is the recommended setting for EVA active-active arrays except for Vdisks used by an MSCS cluster, which should be set to MRU.

MRU is also suitable for other applications if round robin is undesirable in a specific environment.

- Avoid using Fixed I/O path policy with vSphere 4.x/5.x and an EVA array.
- Configure round robin advanced parameters to IOPS=1 for vSphere 4.x/5.x.
- For normal production I/O, avoid using Fixed_AP I/O path policy with vSphere 4.1 or its equivalent Fixed I/O path policy with vSphere 5.x and an EVA array.

¹³ EVA4400 only supports a maximum of 96 drives. Hence 7.2K RPM drives can't meet the minimum number required for adequate VAAI performance.

However, you can leverage Fixed_AP I/O path policy (vSphere 4.1) and Fixed I/O path policy (vSphere 5.x) to quickly rebalance the Vdisk configuration after a controller has been restored from failure. Use just one vSphere 4.1/5x server from the cluster; ensure the array is not under heavy load.

How do I simplify storage management, even in a complex environment with multiple storage systems?

- In multi-vendor, ALUA-compliant SAN environment, you should select the default PSP for the VMW_SATP_ALUA based on the PSP that has been recommended for one of the following:
 - The most prevalent array in the SAN
 - The array with the most Vdisks provisioned for vSphere access
- In an exclusively EVA environment, change the default PSP option for VMW_SATP_ALUA to VMW_PSP_RR.
- Round robin I/O path policy is recommended for EVA active-active arrays. MRU is also suitable if round robin is not desired in a particular environment.
- Configure MSCS cluster Vdisks to use MRU I/O path policy. Since the recommended default setting for all EVA Vdisks is round robin, you must manually configure MSCS Vdisks to MRU.
- Alternate the controller ownership of EVA Vdisks between Controller A and Controller B by configuring the Path-A-Failover/Failback or Path-B-Failover/Failback setting.
- With vSphere 4.1/5x, create a new SATP rule for each storage system.
- Use the same Vdisk ID for all vSphere servers in the same cluster.
- Use a simplified name for your datastores and be consistent, thus accommodating vSphere hosts you may later add to the cluster.
- To properly align the filesystem, use the vSphere client when creating a datastore.
- When naming a datastore, use the same name you selected in Command View EVA when creating the logical unit/Vdisk.
- Utilize HP Insight Control Storage Module for vCenter to save time and improve efficiency by mapping, monitoring, provisioning, and troubleshooting EVA storage directly from vCenter.

How can I best monitor and tune the EVA array in order to optimize performance?

- If increasing the queue depth at the HBA level, also increase the value of the vSphere 4.x advanced parameter Disk.SchedNumReqOutstanding.
- When using VMs with I/O-intensive workloads, consider using paravirtualized virtual adapters for the VM's data logical units, which can provide a 10% 40% performance improvement, depending on the workload.
- Unless using Windows Vista, Windows 7, or Windows Server 2008, ensure that data drives within the guest OS are properly aligned.
- When using VMs that generate large-sized I/Os, consider setting the vSphere 4.x/5.x advanced parameter Disk.DiskMaxIOSize to 128 KB to increase storage performance.
- HP recommends leaving QFullSampleSize and QFullThreshold at their default disabled values and, instead, investigating the root cause of any I/O congestion. If you do choose to enable adaptive queuing, HP recommends the following settings:
 - QFullSampleSize = 32
 - QFullThreshold = 4
- Use EVAperf to monitor EVA performance in order to make proactive adjustments.
- VMFS datastore must be aligned to either a 64KiB or 1MB boundary for use with HP EVA Storage VAAI integration.
- For improved performance, when performing zeroing activities on two or more Vdisks concurrently, it is best to have the Vdisks ownership evenly spread across controllers.
- XCOPY operations can benefit from increased performance when different EVA controllers own the source and destination datastores.
- When the EVA is in degraded mode, avoid using VAAI operations.

- When using VAAI on Vdisks that are in snapshot, snapclone, mirror clone or continuous access relationships VAAI performance may be throttled.
- Minimize the number of concurrent VAAI clone and/or zeroing operations to reduce the impact on overall system performance.
- Ensure the HP EVA Storage is configured with an adequate number of drives when using VAAI. Refer to Table 8 for guidance.

How do I maintain the availability of Command View EVA deployed in a VM?

• HP recommends deploying Command View EVA (CV EVA) on the local datastore of a vSphere server. However, if a SAN-based deployment s required, then load CV EVA on to multiple EVAs to ensure that the management interface remains available. If CVA EVA were deployed on a single VM, the management interface would be lost if the particular EVA became inaccessible.

Summary

In most environments, the best practices highlighted in this document can help you reduce configuration time and improve storage performance. However, as with all best practices, you must carefully evaluate the pros and cons of the recommendations presented herein and assess their value in your particular environment.

In addition to serving as a reference guide for anyone configuring an EVA-based SAN in conjunction with vSphere 4.x/5.x, this document also provides valuable information about the latest VMware technologies, such as the multipathing storage stack.

Glossary

Array	In the context of this document, an array is a group of disks that is housed in one or more disk enclosures. The disks are connected to two controllers running software that presents disk storage capacity as one or more virtual disks. The term "array" is synonymous with storage array, storage system, and virtual array.
Controller firmware	The firmware running on each controller within the array manages all aspects of array operation, including communications with Command View EVA.
DR group	A data replication (DR) group is a logical group of virtual disks that is part of a remote replication relationship with a corresponding group on another array.
Default disk group	The default disk group is the disk group created when the array is initialized. This group must contain a minimum of eight disks, with its maximum size being the number of installed disks.
Disk group	A disk group is a named group of disks that have been selected from disks that are available within the array. One or more virtual disks can be created from a disk group.
ESX/ESXi	ESX/ESXi is the hypervisor component of VMware vSphere.
EVA	The HP Enterprise Virtual Array (EVA) Storage product allows pooled disk capacity to be presented to hosts in the form of one or more variably-sized physical devices. The EVA consists of disks, controllers, cables, power supplies, and controller firmware. An EVA may be thought of as a storage system, a virtual array, or a storage array. In this paper the term EVA is also used to refer to classic HP EVA4400/6400/8400 Storage products and the HP EVA P6000 Storage.
Failover	The failover process causes one controller to assume the workload that was previously running on a failed, companion controller. Failover continues until the failed controller is once again operational.
Host	A host is a computer that runs user applications and uses information stored on an array.
LU	The logical unit (LU) is a SCSI convention used to identify elements of a storage system; for example, hosts see a virtual disk as an LU. An LU is also referred to as a Vdisk. The logical unit number (LUN) assigned by the user to a Vdisk for a particular host is the LUN at which that host will see the virtual disk.
LUN	The logical unit number (LUN) is a SCSI convention used to enumerate LU elements; for example, the host recognizes a particular Vdisk by its assigned LUN.
Management server	A management server runs management software such as HP Command View EVA and HP Replication Solutions Manager.
RDM	VMware Raw Device Mapping (RDM) technology allows an LU to be mapped directly from an array to a VM.
Server-based management	The term "server-based management" implies management from a server.

SAN	A Storage Area Network (SAN) is a network of storage devices that includes the initiators required to store information on and retrieve information from these devices; the SAN includes a communications infrastructure.
SSSU	The Storage System Scripting Utility (SSSU) is an HP command-line interface that can be used to configure and control EVA arrays.
Storage area network	See "SAN".
Storage array	Generic term for an EVA.
Storage system	Generic term for an EVA.
Storage System Scripting Utility	See "SSSU".
Storage array	Generic term for an HP EVA Storage product.
UUID	The Unique Universal Identifier (UUID) is a unique, 128-bit identifier for each component of an array. UUIDs are internal system values that cannot be modified by the user.
Vdisk	See "virtual disk".
Virtual array	Generic term for an EVA; see also "virtual disk".
Virtual disk	A virtual disk provides variable disk capacity that is defined and managed by the array controller. This capacity is presented to hosts as a disk. A virtual disk may be called a Vdisk in the user interface.
Vraid	Vraid is an EVA representation of RAID levels.
VM	A virtual machine is a guest operating system that runs on a vSphere (ESX) host.
WWNN	World Wide Node Name
WWPN	World Wide Port Name

Appendix A – Using SSSU to configure the EVA

The sample SSSU script provided in this appendix creates and presents multiple Vdisks to vSphere hosts.

The script performs the following actions:

- Create a disk group with 24 disks.
- Set the disk group sparing policy to single-drive failure.
- Create Vdisk folders.
- Add two vSphere hosts and their respective HBA presentation to the EVA and assign the appropriate host profiles.
- Create five Vdisks and present each to both vSphere hosts.

Sample script

More information

For more information on the SSSU command set, refer to the SSSU user guide, which can be found in the document folder for the Command View EVA install media.

Appendix B – Miscellaneous scripts/commands

This appendix provides scripts/utilities/commands for the following actions:

- Change the default PSP for VMW_SATP_ALUA.
- Set the I/O path policy and attributes for each Vdisk.
- Configure the disk SCSI timeout for Windows and Linux guests.

Changing the default PSP

This command changes the default PSP for VMW_SATP_ALUA:

```
For ESX 4.x:
esxcli nmp satp setdefaultpsp -s VMW_SATP_ALUA -P VMW_PSP_RR
For ESXi 5.x:
```

```
esxcli storage nmp satp set -s VMW_SATP_ALUA -P VMW_PSP_RR
```

Setting the I/O path policy and attributes¹⁴

This script automatically sets the I/O path policy to round robin and also sets the I/O path attributes for each Vdisk:

Note

This script should only be used for environments with EVA Vdisks connected to vSphere 4.x/5.x servers.

For ESX 4.x

```
for i in 'esxcli nmp device list | grep ^naa.600';do esxcli nmp device setpolicy -P VMW_PSP_RR -d $i;esxcli nmp roundrobin setconfig -t iops -I 1 -d $i; done
```

For ESXi 5.x

```
for i in 'esxcli storage nmp device list | grep ^naa.600';do esxcli storage nmp
device set -P VMW_PSP_RR -d $i;esxcli storage nmp psp roundrobin deviceconfig set -
t iops -I 1 -d $i;done
```

Configuring the disk SCSI timeout for Windows and Linux guests

Change the disk SCSI timeout setting to 60 seconds.

Windows guest

For a VM running Windows Server 2003¹⁵ or earlier, change the value of the HKEY_LOCAL_MACHINE/SYSTEM/CurrentControlSet/Services/Disk/TimeoutValue registry setting to **3c** (that is, **60** expressed in hexadecimal form).

A reboot is required for this change to take effect.

¹⁴ When cutting and pasting the scripts referenced beware of hidden characters that may cause the scripts to fail. Allows copy in a text editor that will strip hidden characters before running this script.

¹⁵ In Windows Server 2008, the SCSI timeout defaults to 60 seconds.

Linux guest

Use one of the following commands to verify that the SCSI disk timeout has been set to a minimum of 60 seconds:

cat /sys/bus/scsi/devices/W:X:Y:Z/timeout

or

cat /sys/block/sdX/device/timeout

If required, set the value to 60 using one of the following commands:

echo 60 > /sys/bus/scsi/devices/W:X:Y:Z

or

echo 60 | cat /sys/block/sdX/device/timeout

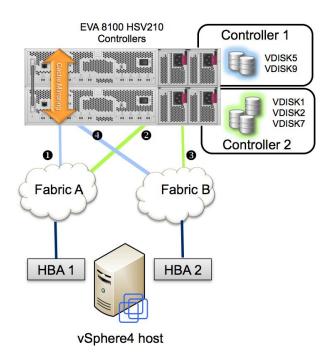

where W:X:Y:Z or sdX is the desired device.

No reboot is required for these changes to take effect.

Appendix C - Balancing I/O throughput between controllers

The example described in this appendix is based on an environment (shown in Figure C-1) with balanced Vdisk access but imbalanced I/O access. The appendix explores the steps taken to balance I/O access.

Figure C-1. Sample vSphere 4.x/5.x environment featuring an HP 8100 Enterprise Virtual Array with two four-port HSV210 controllers

Vdisks are balanced, as recommended in this document, with two Vdisks owned by Controller 1 and three by Controller 2; however, you must also ensure that I/Os to the controllers are balanced. Begin by using the EVAperf utility to monitor performance statistics for the EVA array.

Run the following command:

evaperf hps -sz <array_name> -cont X -dur Y

where X is the refresh rate (in seconds) for statistics and Y is the length of time (in seconds) over which statistics are captured.

Figure C-2 provides sample statistics.

Note

The statics shown in Figure C-2 are not representative of actual EVA performance and can only be used in the context of the example provided in this appendix, which is intended to illustrate the benefits of round robin I/O path policy and ALUA-compliance rather than presenting actual performance.

Figure C-2. I/O routes

EV/	EVAPerf - evaperf hps -sz EVA-DC2 -cont 2 -dur 666666666666666666666666666666666666											
Name	Read Req∕s	Read MB∕s	Read Latency (ms)	Write Req⁄s	Write MB/s				Ctlr	Node		
FP1 FP2	 0 0	0.00 0.00	0.0 0.0	1170	152.94	35.0 35.4	31	5000-1FE1-5009-76FC 5000-1FE1-5009-76FD	008R	EVA-DC2		
FP3 FP4 FP1	9 9 9	0.00 0.00 0.00	0.0 0.0 0.0	9 9 9	0.00 0.00 0.00	0.0 0.0 12.7	ø	5000-1FE1-5009-76FE 5000-1FE1-5009-76FF 5000-1FE1-5009-76F8	008R	EVA-DC2		
FP2 FP3 FP4	9 9 9	0.00 0.00 0.00	0.0 0.0 0.0	0 0 0	0.00 0.00 0.00	11.3 0.0 0.0	Ø	5000-1FE1-5009-76F9 5000-1FE1-5009-76FA 5000-1FE1-5009-76FB	Z07Y	EVA-DC2		
F1-4	Ð	0.00	0.0	Ð	0.00	0.0	9	2000-11.FT-2003-401.P	2071	LVH-DG2		

In this example, even though the EVA array has a total of eight controller ports (four on each controller), all I/O seems to be routed through just two ports on Controller 1. Note that SAN zoning is only allowing each HBA to see ports 1 and 2 of each controller, explaining why no I/O is seen on ports 3 and 4 even though round robin I/O path policy is being used.

The system is unbalanced because, despite having three Vdisks preferred to Controller 2, most of the workload is handled by Controller 1.

You can verify this imbalance by reviewing the appropriate Vdisk path information. Figure C-3 provides path information for Vdisk9; Figure C-4 provides information for Vdisk5.

Figure C-3. Path information for Vdisk9

For a more granular view of throughput distribution, use the following command:

evaperf vd -sz <array_name> -cont X -dur Y

This command displays statistics at the EVA Vdisk level, making it easier for you to choose the appropriate Vdisk(s) to move from one controller to the other in order to better balance controller throughputs.

Moving the chosen Vdisk from one controller to the other

To better balance throughput in this example, Vdisk5 is being moved to Controller 2.

This move is accomplished by using Command View EVA to change the managing controller for Vdisk5, as shown in Figure C-7.

Figure C-7. Using Command View EVA to change the managing controller for Vdisk5 from Controller A to Controller B

Adapter: 50				
Adapter: 50				

I/O is now round robin on FP1 and FP2 of Controller B.

Validating the better balanced configuration

You can review the output of EVAperf (as shown in Figure C-9) to verify that controller throughput is now better balanced. Run the following command:

evaperf hps -sz <array_name> -cont X -dur Y

Figure C-9.	Improved I/O	distribution
-------------	--------------	--------------

lame	Read Req∕s	Read MB∕s	Read Latency (ms)	Write Req∕s	Write MB/s	Write Latency (ms)		Port WWN	Ctlr	Node

P4	Ø	0.00	0.0	Ø	0.00	0.0	Ø	5000-1FE1-5009-76FE	Z07Y	EUA-DO

The system now has much better I/O distribution.

Appendix D – Caveat for data-in-place upgrades and Continuous Access EVA

The vSphere datastore may become invisible after one of the following actions:

- Performing a data-in-place upgrade from one EVA controller model to another
- Using Continuous Access EVA to replicate from one EVA model to another

Following these actions, ESX treats the new datastore as being a snapshot and, by default, does not display it.

Why is the datastore treated as a snapshot?

When building the VMFS file system on a logical unit, ESX writes metadata to the Logical Volume Manager (LVM) header that includes the following information:

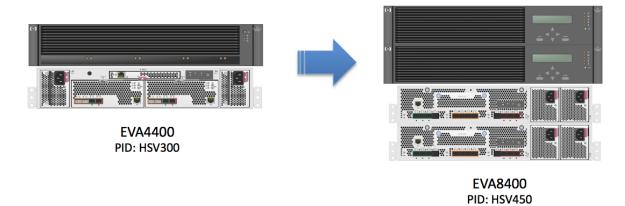

- Vdisk ID (such as Vdisk 1)
- SCSI inquiry string for the storage (such as HSV300); also known as the product ID (PID) or model string
- Unique Network Address Authority (NAA)-type Vdisk identifier, also known as the Worldwide Node LUN ID of the Vdisk

If any of these attributes changes after you create the new datastore, ESX treats the volume as a snapshot because the new Vdisk information will not match the metadata written on disk.

Example

Consider the data-in-place migration example shown in Figure D-1, where existing HSV300 controllers are being replaced with HSV450 controllers.

Figure D-1. Replacing EVAs and controllers

After the upgrade, all Vdisks will return "HSV450" instead of "HSV300" in the standard inquiry page response. This change in PID creates a mismatch between LVM header metadata and the information coming from the Vdisk.

Note

A similar mismatch would occur if you attempted to use Continuous Access EVA to replicate from the EVA4400 to the EVA8400.

When such a mismatch occurs, datastores are treated as snapshots and are not exposed to ESX. However, vSphere 4.x allows you to force-mount or re-signature these snapshots to make them accessible. For more information, refer to the following VMware Knowledge Base (KB) articles: <u>1011385</u> and <u>1011387</u>.

Appendix E – Configuring VMDirectPath I/O for Command View EVA in a VM

This appendix describes how to configure VMDirectPath I/O in a vSphere 4.x environment for use with Command View EVA. An example is presented.

Note that Command View EVA in a VM is not supported with VMDirectPath I/O with ESXi 5.

Note

The configuration described in this appendix is only provided for the purposes of this example.

Sample configuration

Server configuration

Table E-1 summarizes the configuration of the vSphere server used in this example.

This appendix shows how to assign HBA3 to VM2 in vSphere 4.x.

EVA configuration

This example uses four ports on an EVA8100 array (Ports 1 and 2 on each controller). A single EVA disk group was created.

The EVA configuration is summarized in Table E-2.

Component	Description			
EVA disk group	Default disk group, w	ith 13 physical disks		
Vdisks	\VMDirectPath\ESX-V	/MFS-LUN1: 50GB	ESX LUN 1	Path A Failover/Failback

	VM2	Windows Server 2008		

Fibre Channel configuration

This example uses two HP 4/64 SAN switches, with a zone created on each.

The Fibre Channel configuration is summarized in Table E-3.

Table E-3. Fibre Channel configuration summary

Component	Description	WWN
Switch 1, Zone 1	Controller 1, Port 1	5000-1FE1-0027-07F8
	Controller 2, Port 1	5000-1FE1-0027-07FC
	HBA 1, Port 1	5006-0B00-0063-A7B4
	VM2, HBA3, Port 1	1000-0000-C97E-CA72
Switch 2, Zone 1	Controller 1, Port 1	5000-1FE1-0027-07F8
	Controller 2, Port 1	5000-1FE1-0027-07FC
	HBA 1, Port 1	5006-0B00-0063-A7B4
	VM2, HBA3, Port 1	1000-0000-C97E-CA72

Configuring the vSphere host

After the SAN topology and array-side configuration have been completed, you can configure HBA3 to be used as a VMDirectPath HBA for the Windows Server 2008 VM.

Note

If desired, you could configure VMDirectPath HBAs before configuring the SAN.

This appendix outlines a procedure for configuring VMDirectPath¹⁶.

First, complete the following prerequisites:

- Open a PuTTY (ssh client) session¹⁷ to the particular vSphere host.
- Open a vSphere Client connection to the vSphere host.
- Pre-install the VMs (for example, as VMs installed on a VMDK on a SAN datastore or a local datastore).

Note

Refer to Configuring EVA arrays for more information on placing VMs.

¹⁶ This procedure assumes that you have never performed this task before. Alternate methods are available.

¹⁷ While not necessary, an ssh session may be useful the first time you perform this procedure.

The procedure is as follows:

1. Identify which HBAs are present on the vSphere server by issuing the following command:

[root@lx100 ~]# lspci | grep "Fibre Channel"

This command provides a quick view of the HBAs in your system and their respective PCI hardware IDs. Alternatively, you can view HBAs via the vSphere Client; however, PCI hardware IDs would not be shown.

The output to the above command is similar to that shown in Figure E-2.

Figure E-2. Identifying the HBAs present on the vSphere server

10:00.0 Fibre Channel: QLogic Corp ISP2432-based 4Gb Fibre Channel to PCI Express HBA (rev 02)

10:00.1 Fibre Channel: QLogic Corp ISP2432-based 4Gb Fibre Channel to PCI Express HBA (rev 02)

1b:00.0 Fibre Channel: QLogic Corp ISP2532-based 8Gb Fibre Channel to PCI Express HBA (rev 02)

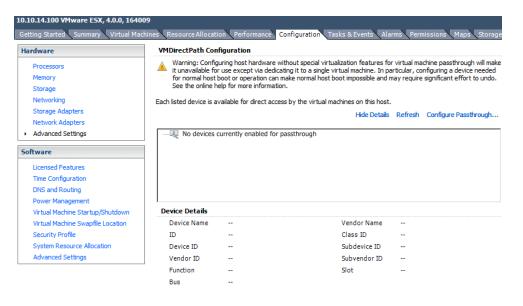

1b:00.1 Fibre Channel: QLogic Corp ISP2532-based 8Gb Fibre Channel to PCI Express HBA (rev 02)

21:00.0 Fibre Channel: Emulex Corporation LPe12000 8Gb Fibre Channel Host Adapter (rev 03)

21:00.1 Fibre Channel: Emulex Corporation LPe12000 8Gb Fibre Channel Host Adapter (rev 03)

2. Access the vSphere host through vSphere Client. Select the **Configuration** tab and click on **Advanced Settings** in the **Hardware** section, as shown in Figure E-3, to determine if passthrough (VMDirectPath) is supported.

Figure E-3. Indicating that no devices have been enabled for VMDirectPath

The screen displays a warning indicating that configuring a device for VMDirectPath will render that device unusable by vSphere.

In this example, no devices are currently enabled for VMDirectPath I/O.

However, if your server hardware does not support Intel® Virtualization Technology for Directed I/O (VT-d) or AMD Extended Page Tables (EPT), Nested Page Tables (NPT), and Rapid Virtualization Indexing (RVI), it cannot support VMDirectPath. In this case, the **Advanced Settings** screen would be similar to that shown in Figure E-4, which indicates that the host does not support VMDirectPath.

Figure E-4. Indicating that, in this case, the server hardware is incompatible and that VMDirectPath cannot be enabled

Passthrough Configuration

Warning: Configuring host hardware without special virtualization features for virtual machine passthrough will make it unavailable for use except via dedicating it to a single virtual machine. In particular, configuring a device needed for normal host boot or operation can

4. Select the desired devices for VMDirectPath; select and accept the passthrough device dependency check shown in Figure E-6.

IMPORTANT

If you select **OK**, the dependent device is also configured for VMDirectPath, regardless of whether or not it was being used by ESX. If your server is booting from SAN, be careful not to select the incorrect HBA; your server may subsequently fail to reboot.

Figure E-6. Warning about device-dependency

As shown in Figure E-7, the VMDirectPath Configuration screen reflects the changes you have made. Device icons indicate that the changes will only take effect when the server is rebooted.

Figure E-7. Indicating that four HBA ports have been enabled for VMDirectPath but that these changes will not take effect until a server reboot

VMDirectPath Configuration

Warning: Configuring host hardware without special virtualization features for virtual machine passthrough will make it unavailable for use except via dedicating it to a single virtual machine. In particular, configuring a device needed for normal host boot or operation can make normal host boot impossible and may require significant effort to undo. See the online help for more information.

Each listed device is available for direct access by the virtual machines on this host.

♦ Changes made to some of the devices below will not take effect until the host is restarted.

7. Issue the following command to validate the VMDirectPath-enabled HBA ports:

[root@lx100 ~] # vmkchdev -l | grep vmhba

Review the resulting output, which is shown in Figure E-9.

Figure E-9. Validating that four HBA ports have indeed been enabled for VMDirectPath

000:31.2 8086:3a20 103c:330d vmkernel vmhba1 005:00.0 103c:323a 103c:3245 vmkernel vmhba0 016:00.0 1077:2432 103c:7041 vmkernel vmhba6 016:00.1 1077:2432 103c:7041 vmkernel vmhba7 027:00.0 1077:2532 103c:3263 passthru vmhba9 027:00.1 1077:2532 103c:3263 passthru vmhba11 033:00.0 10df:f100 103c:3282 passthru vmhba12

As expected, the following devices have been enabled for VMDirectPath and are no longer claimed by the VMkernel.

- Hardware ID 1b:00.0/1b:00.1 (hexadecimal), 027:00.0/027:00.1 (decimal)
- Hardware ID 21:00.0/21:00.1 (hexadecimal), 033:00.0/033:00.1 (decimal)

Furthermore, the vSphere Client **Storage Adapters** window no longer displays vmhba9, 10, 11, and 12. See figures E-1 and E-2.

The VMDirectPath HBAs can now be assigned to VMs.

Note

The changes you have just made are stored in the **/etc/vmware/esx.conf** file.

Configuring the array

Use Command View EVA to perform the following steps:

- 1. Create the Vdisks.
- 2. Add the hosts:
 - vSphere server: Set the Command View EVA host mode to VMware
 - VM2: Set the Command View EVA host mode to Windows Server 2008
- 3. Add Vdisks presentation.

Configuring the VM

Caveats

- HBA ports are assigned to the VM one at a time, while the VM is powered off.
- The VM must have a memory reservation for the fully-configured memory size.
- You must not assign ports on the same HBA to different VMs, or the same HBA to various VMs. Though such configurations are not specifically prohibited by vSphere client, they would result in the VM failing to power on. You would receive a message such as that shown in Figure E-10.

Figure E-10. Message resulting from a misconfiguration

Error		×
8	Device 027:00.1 is already in use	
	ОК	

Prerequisites

Before beginning the configuration, complete the following prerequisites:

- Open a vSphere Client connection to the vSphere host.
- Pre-install the VM (for example, on a VMDK on a local or SAN datastore).
- Obtain console access to the VM through vSphere Client.

Note

Refer to Configuring EVA arrays for more information on placing VMs.

Procedure

Carry out the following steps to add VMDirectPath devices to a selected VM:

- 1. From the vSphere client, select VM2 from the inventory, ensuring that it is powered off.
- 2. Right-click on the VM and select Edit Settings.
- 3. Select the Hardware tab and then click on Add.
- 4. Select **PCI Device** and then click on **Next**, as shown in Figure E-11.

Figure E-11. Selecting PCI Device as the type of device to be added to the VM

🛃 Add Hardware	×				
Device Type What sort of device do you wish to add to your virtual machine?					
Device Type Select PCI/PCIe Device Ready to Complete	Choose the type of device you wish to add.				
Help	< Back Next > Cancel				

5. From the list of VMDirectPath devices, select the desired device to assign to the VM, as shown in Figure E-12.

In the example, select Port 1 of HBA3 (that is, device 21:00.0).

For more information on selecting devices, refer to <u>Caveats</u>.

Figure E-12. Selecting VMDirectPath devices to be added to the VM

Choose PCI Device Which of the present PCI	CIE devices would you like to add?
Device Type Select PCI/PCIe Device Ready to Complete	Connection Specify the physical PCI/PCIe Device to connect to: Ib:00.0 QLogic Corp ISP2532-based 8Gb Fibre Channel to PCI Express HBA Ib:00.1 QLogic Corp ISP2532-based 8Gb Fibre Channel to PCI Express HBA Ib:00.1 QLogic Corp ISP2532-based 8Gb Fibre Channel to PCI Express HBA 21:00.0 Emulex Corporation IPe12000 8Gb Fibre Channel Host Adapter It Wint Ot be able to be suspender, to have snapshots taken or restored, or to participate in VMotion. Adding a PCI Passtbrough device to this VM will automatically set its minimum memory reservation equal to its memory size.
Help	< Back Next > Cancel

- 6. Repeat Step 5 to assign Port 2 of HBA2 (that is, device 21:00.1) to the VM.
- 7. Use vSphere Client to open a console window to the Windows Server 2008 VM.
- 8. Use Device Manager on the VM to verify that the Emulex HBA has been assigned to this VM.

If zoning has already been implemented (see <u>Fibre Channel configuration</u>), you can now follow the <u>HP Command</u> <u>View EVA installation guide</u> to install Command View EVA, as you would on a bare-metal (physical) server.
